20. ABSTRACT (Continued).

for predicting water quality and eutrophication potential, is the objective of EWOOS Work Unit IE.

This report documents the establishment of a computerized data base containing water quality, hydrologic, and morphometric information for 299 reservoirs operated by the U. S. Army Corps of Engineers (CE). Sources of information included STORET (including the National Eutrophication Survey data), U. S. Department of Agriculture sedimentation survey data sheets, project design memoranda and CE District and Division data files. Supplemental sources included maps, project brochures, and reports. Programming for data manipulation and analysis is in the PL/I and FORTRAN IV languages. BMDP and SAS programs were employed during preliminary analysis. The data base presently contains over 2.5 million water quality observations taken at 4451 stations located in or around 271 CE reservoirs.

Methods for estimating volume and area variations with elevation, required for volume-averaging of water quality data and for calculating material loadings, have been developed. Preliminary analyses have also been performed to assess the importance of spatial and temporal variability to the computation of representative water quality values.

Appendix A contains data inventories for each project included in the data base.

## PREFACE

This report was prepared by Dr. William W. Walker, Jr., Environmental Engineer, Concord, Mass., for the U. S. Army Engineer Waterways Experiment Station (WES) under Contract DACW39-78-0053 dated 7 June 1978. The study forms part of the Environmental and Water Quality Operational Studies (EWQOS) Work Unit IE, Simplified Techniques for Predicting Reservoir Water Quality and Eutrophication Potential. The EWQOS Program is sponsored by the Office, Chief of Engineers, and is assigned to the WES under the purview of the Environmental Laboratory (EL).

The study was under the direct WES supervision of Dr. Robert H. Kennedy and the general supervision of Mr. Donald L. Robey, Chief, Water Quality Modeling Group; Dr. Rex L. Eley, Chief, Ecosystem Research and Simulation Division; Dr. Jerry Mahloch, Program Manager, EWQOS; and Dr. John Harrison, Chief, EL.

The Commanders and Directors of WES during this study were COL John L. Cannon, CE, and COL Nelson P. Conover, CE. The Technical Director was Mr. Fred R. Brown.

CONVERSION FACTORS, U. S. CUSTOMARY TO METRIC (SI)  
UNITS OF MEASUREMENT

U. S. customary units of measurement used in this report can be converted to metric (SI) units as follows:

Multiply	By	To Obtain
acres	4046.873	square metres
acre-feet	1233.482	cubic metres
cubic feet per second	0.02831685	cubic metres per second
Fahrenheit degrees	5/9	Celsius degrees or Kelvins*
feet	0.3048	metres
inches	2.54	centimetres
miles (U. S. statute)	1.609344	kilometres
pounds (mass) per cubic foot	16.01846	kilograms per cubic metre
square miles	2.589988	square kilometres
tons (2000 lb, mass)	907.1847	kilograms

---

\* To obtain Celsius (C) temperature readings from Fahrenheit (F) readings, use the following formula:  $C = (5/9)(F - 32)$ . To obtain Kelvin (K) readings, use:  $K = (5/9)(F - 32) + 273.15$ .

EMPIRICAL METHODS FOR PREDICTING

EUTROPHICATION IN IMPOUNDMENTS

PHASE I: DATA BASE DEVELOPMENT

PART I: INTRODUCTION

1. This report documents the development of a data base describing certain water quality aspects of reservoirs operated by the U. S. Army Corps of Engineers (CE). The data base includes information on project location, morphometry, water quality, hydrology, and sedimentation. As part of the Environmental and Water Quality Operational Studies (EWQOS) Program being conducted by the Office, Chief of Engineers, U. S. Army, this work has been conducted to provide groundwork for assessing empirical approaches to describing and predicting reservoir trophic status.

2. One basic strategy employed in assembling this data base has been to utilize existing, centralized sources of information first. These have included nationwide data bases maintained by various federal agencies, as well as a few sources of data tabulated at a regional level. A framework has been designed and implemented for storing and accessing this information, with flexibility for updating and general access, so as to meet the specific objectives of this project. Having utilized centralized data sources to their fullest extent, data gaps have been identified and used to set priorities for locating and incorporating information from relatively diffuse sources, such as specific project design memoranda and other published or unpublished reports dealing with individual projects. This stage-wise data-gathering procedure has been designed with efficiency and cost-effectiveness in mind.

3. Another basic strategy which has been employed in compiling water quality and hydrologic data has been to assemble individual observations in space and time (i.e., "raw data"), rather than average values. This strategy accomplishes the following:

- a. It provides for the broadest possible range of future uses of the data base.
- b. It eliminates possible variations due to the use of different averaging procedures.
- c. It provides a basis for error analysis and assessment of data adequacy in future model testing.

These advantages must be weighed against the major disadvantage of the approach--it involves management of a large amount of information. The water quality file presently contains two million observations taken at 4451 stations located in or around 271\* CE projects.

4. Management of these types and quantities of information entails use of a consistent framework. One basic strategy has been to tag each bit of information with district, project, and data source codes. While the validity of the information at its original source cannot be substantiated, use of a systematic approach in building the data base insures that the data are transferred and accessed properly. Keeping track of original data sources provides a means of checking any piece of information at its source and identifying discrepancies among multiple data sources for the same value. The latter provides one indication of data and source reliability. Another validity test involves checking for internal consistency in a given set of values. For example, the morphometric profiles have been tested by comparing reported volumes at any elevation with the integral of reported areas with respect to depth. The third validity test involves distribution of portions of the data base to district offices for verification and editing. This entails their cooperation and assumes that district-level sources of information for specific projects are the most accurate. This approach has been taken for upgrading the morphometric data file with reasonable success.

5. In its current state, the data base is a collection of information in a well-defined framework. It is not a user-oriented system designed for frequent interactive use. Such a system would require

---

\* A total of 299 projects are included in the data base; no water quality data have been located for 28.

extensive software development geared to a specific computer system and to the intended uses of the information in various areas of reservoir management. The scope of this project has been limited to compiling the information, organizing it, and extracting portions that are directly relevant to analysis of eutrophication problems in reservoirs. With additional software development and systems programming, the data base could be made accessible for more generalized purposes.

6. The complete data base consists of a collection of computer files, reports, data forms, and maps. As discussed above, each piece of information is referenced by CE district, project, and data source codes. Part II of this report describes the facilities, methods, and agency contacts used in this work. Part III describes the general structure of the data base. Parts IV through XI document the sources and approaches used in compiling each element and present data inventories. Parts XII-XIV summarize results of specific analyses which lay the groundwork for use of the data base in Phase II of this project. These analyses cover the following topics: (XII) numerical characterization of reservoir hypsographic curves; (XIII) assessment of the variability of trophic state indicators in reservoirs; and (XIV) testing of methods for estimation of nutrient budgets. Conclusions and Recommendations are given in Part XV and XVI, respectively. Appendix A contains data inventories by project and district.

## PART II: FACILITIES AND METHODS

7. Compilation and manipulation of the various data files documented in this report have been done on an IBM 370-168 computer maintained by the Information Processing Center of the Massachusetts Institute of Technology (MIT). This facility has been used in a batch processing mode (OS/VSI) and in an interactive mode through IBM's Conversational Monitoring System (CMS). Three media have been used for data storage where appropriate: (1) 9-track tapes (6250 bytes per inch); (2) 3350 disc packs (OS and CMS); and (3) cards. Copies of the current versions of all files have been transferred to tapes for secure storage and future access.

8. While most of the information used to assemble the data base has been read from tapes supplied by various agencies, some files (in particular, the project lists, morphometry, and sedimentation files) have been assembled from tabulated data. In these cases, cards have been used for data entry. Keypunching has been done and verified using contract services offered by MIT.

9. Programming for data manipulation and analysis is in the PL/I and FORTRAN IV languages. The Biomedical Computer Program package (BMDP)<sup>1</sup> and SAS<sup>2</sup> have also been used in preliminary data analyses. Plots have been produced with a Calcomp line plotter.

10. Access to the Environmental Protection Agency (EPA) STORET system<sup>3</sup> has been acquired through the cooperation of the Water Quality Laboratory of the New England Division of the Corps of Engineers. The staff of the Systems Analysis Branch of the EPA Region I Office in Boston has been helpful in submitting STORET retrievals. The identification of water quality and quantity monitoring stations has been done partially using the services of the National Water Data Exchange of the U. S. Geological Survey in Reston, Virginia. The Corvallis Environmental Research Laboratory of the U. S. Environmental Protection Agency has provided reports and data files from the National Eutrophication Survey (NES)<sup>4</sup>. Sedimentation survey sheets have been obtained through the

Sedimentation Laboratory of the U. S. Department of Agriculture and the South Technical Service Center of the U. S. Soil Conservation Service in Fort Worth, Texas.

11. Staff members of the Environmental Laboratory of the U. S. Army Engineer Waterways Experiment Station (WES) have provided assistance in extracting and coding morphometric and drainage area data from project design memoranda and in coding water quality data compiled outside of STORET. The Ohio River Division (ORD) of the Corps of Engineers provided tapes containing water quality data gathered by district monitoring programs in that division.

### PART III: DATA BASE STRUCTURE

12. Figure 1 depicts the organization of the data base into eight major file groups:

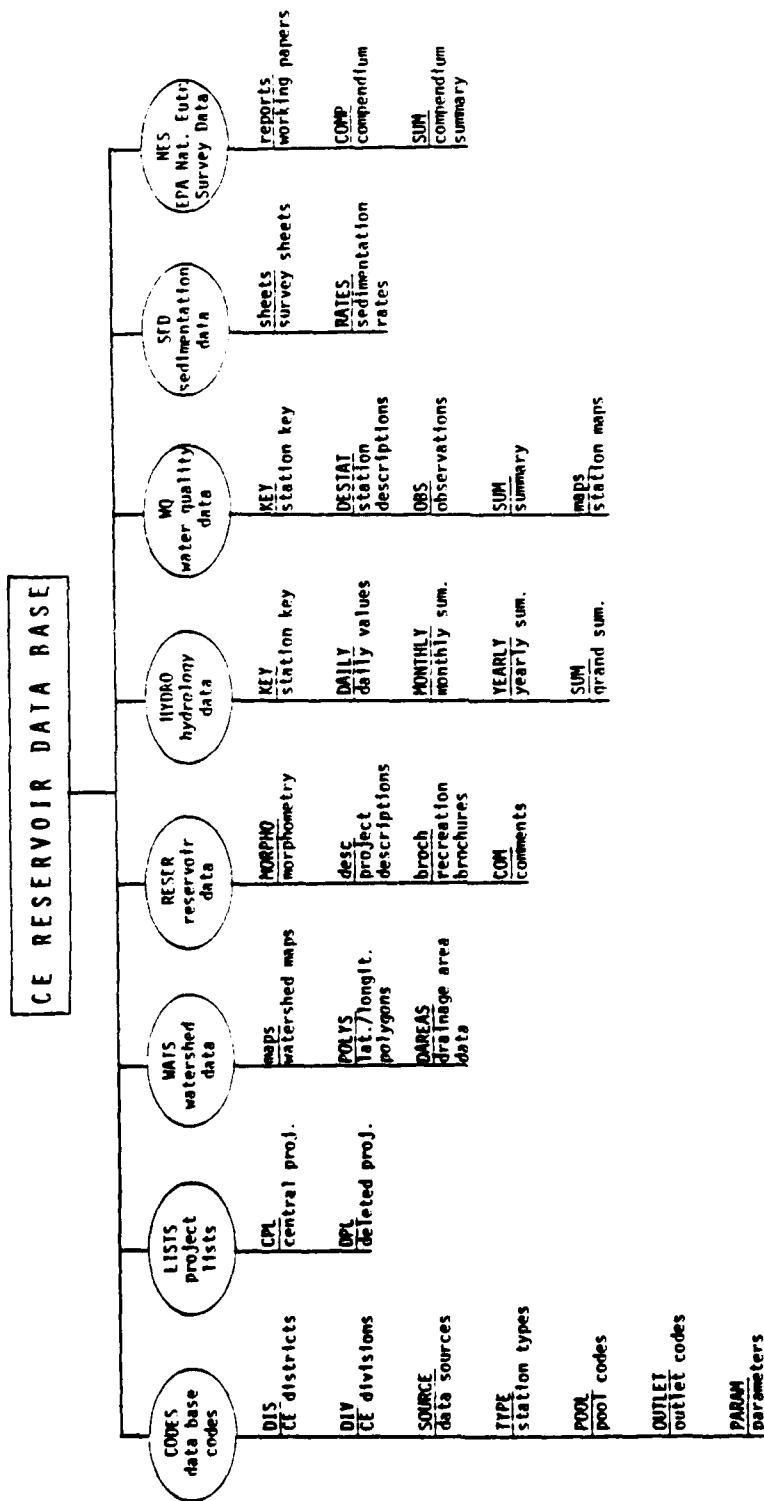

CODES	- Data Base Codes
LISTS	- Project Lists
WATS	- Watershed Characteristics
RESER	- Reservoir Characteristics
HYDRO	- Hydrology Data
WQ	- Water Quality Data
SED	- Sedimentation Data
NES	- EPA National Eutrophication Survey Data

Each group contains a number of computer files, data forms, and/or maps. File names are in two parts. The first refers to the major file group and the second, to the specific file within that group. For example, the water quality station key is given the name WQ.KEY. A lowercase second name indicates that the element is a map or data form (not a computer file).

13. U. S. customary units have been used most extensively in the files. This has facilitated the transfer and verification of information, since most of the original sources of morphometric, drainage area, hydrologic, and sedimentation data were also in U. S. customary units. One exception to this convention is the EPA National Eutrophication Survey Compendium<sup>4</sup> file, which was supplied by the EPA in metric units.

14. The development, structure, and contents of each file group are discussed in the following sections. The sources and approaches used in compiling the information are described. Each file is characterized with respect to format and content. Since most files are too large for listing, data holdings are summarized in an inventory format, with categories defined by file, variable, and CE division. Data inventories by project and district are included in Appendix A. Record formats for the files described in this report are defined as PL/I data structures.

Figure 1 Elements and Structure of the CE Reservoir Data Base

PART IV: CODES - DATA BASE CODES

15. CODES consists of a group of files which define referencing systems used in various portions of the data base. These include the following:

CODES.DIS	CE District Codes
CODES.DIV	CE Division Codes
CODES.SOURCE	Data Source Codes
CODES.TYPE	Station Type Codes
CODES.POOL	Pool Codes
CODES.OUTLET	Outlet Codes
CODES.PARAM	Parameter Codes

Listings of these files are given in Tables 1 through 5.

16. District and division codes (Table 1) provide a numerical indexing system for each of 36 districts and 10 divisions, respectively. Districts are grouped within divisions. The New England Division is unique in that it is not comprised of districts. In order to permit referencing of all projects at the district level, district number one has been defined to represent the New England Division.

17. Data source codes (Table 2) provide a referencing system for nine data sources which are used frequently in the data base. Identifying each data entry by source provides a basis for validation and sorting out discrepancies among multiple data sources for a given project and characteristic.

18. A total of nine station type codes have been defined for use in the water quality and hydrology files (Table 3). These provide a frame of reference for locating monitoring stations within a given project. Broadly, these permit distinction among stations located on upstream tributaries, within reservoir pools, and in or below reservoir discharge streams. Within-pool stations are further classified as upper-pool, mid-pool, or near-dam. Mid-pool is used as a default for lake stations. The remaining two are used in cases where coordinates, maps, and/or station location descriptions provide an adequate basis for more refined classification. Secondary tributary codes (upstream and downstream from impoundments) have been used only for some EPA

National Eutrophication Survey stations to aid in hydrologic budget computations.

19. Pool and outlet codes (Table 4) are used in the morphometric file. These provide systems for referencing various elevations to pool allocations for specific uses, ranges of operating levels, and locations and types of principal outlets. The systems were initially designed at WES. Additional codes have been added as needed during subsequent morphometric data compilation.

20. The parameter codes file (Table 5)\* is used to reference hydrologic and water quality data. The file contains 94 members, each identified by a water quality parameter code, STORET code<sup>3</sup>, measurement type, and units. The 5-digit STORET code is used in retrieving water quality and hydrologic data from the STORET system. It is also used to identify measurements in the hydrology files. In addition to the 89 basic water quality parameter codes included in the file, there are 11 redundant parameter codes, which have been used in retrieving water quality data from STORET. Redundant codes result from multiple means of expressing a given type of observation (e.g., temperature in degrees C or degrees F or total phosphorus as P or as PO<sub>4</sub>). Redundancies have been eliminated in final data storage by applying appropriate conversion factors in each case.

---

\* Table 5 contains U. S. customary units of measurement. A table of factors for converting U. S. customary units of measurement to metric (SI) units is presented on page 8.

## PART V: LISTS - PROJECT LISTS

21. LISTS, the second major file group, defines the referencing system used for CE projects in the data base. It consists of the following files:

LISTS.CPL - Central Project List  
LISTS.DPL - Deleted Project List

The development and contents of these files are discussed below.

22. The data base is built around a central list of 299 reservoirs which have been identified from various sources and placed in the LISTS.CPL file. The regional distribution of these projects is shown in Figure 2. Breakdowns by CE district and division are given in Table 6. The following have been used as criteria for inclusion:

- a. projects currently operated by the Corps of Engineers.
- b. projects having seasonal or permanent pools.

The second criterion has been applied to eliminate locks and small run-of-the-river impoundments with short hydraulic residence times and little opportunity for inducing water quality changes, at least with respect to eutrophication.

23. The two primary sources of information used to develop an initial project list include a tabulation of CE projects with surface areas greater than 500 acres compiled by Leidy and Jenkins<sup>5</sup> and a map of CE water resource projects<sup>6</sup>. Based upon CE Water Resource Development Reports<sup>7</sup> and information supplied by various CE district offices, the initial list has been screened to eliminate projects which are incomplete, not currently under CE control, and/or do not have appreciable pools. A separate list of impoundments which have been eliminated has been maintained for future reference (LISTS.DPL). Because it has not been feasible within the scope of this project to compile and incorporate data from detailed, project-specific reports, the current project list may contain some impoundments which do not conform to the above criteria. Similarly, some projects may have been missed. Inclusion and/or screening

of additional projects would be possible with more time devoted to compiling and examining detailed reports.

24. The record format used in the LISTS.CPL and LISTS.DPL files is given in Table 7. Files are listed in Tables 8 and 9, respectively. Each project has been assigned a unique, three-digit identification code to facilitate referencing in the data base. The location of each project is identified by CE division, district, state, county, latitude, longitude, and hydrologic unit. Hydrologic unit maps compiled by the U. S. Geological Survey (USGS)<sup>8</sup> have been used to provide basic location data. Reservoirs lying on the boundaries of states, counties, and/or hydrologic units have been referenced based upon dam location. State and county codes refer to the standard federal coding system (FIPS) documented in the EPA's STORET<sup>3</sup> user's manual. The latitudes and longitudes of projects in which surface elevation monitoring stations have been located refer to those stations, which occur most frequently at dam sites. In other situations, coordinates have been approximated from hydrologic unit maps and refer roughly to dam locations.

25. As shown in Table 1, the project list is cross-referenced to three independent data bases:

- a. the EPA National Eutrophication Survey Working Papers<sup>9</sup>.
- b. the U. S. Department of Agriculture (USDA) compilation of reservoir sedimentation data<sup>10</sup>.
- c. the CE project file compiled by Leidy and Jenkins<sup>5</sup>.

The cross-referencing system facilitates access to specific information on projects contained in these sources.

(Sheet 3 of 3)

## PART VI: WATS - WATERSHED CHARACTERISTICS

26. WATS, the third major file group, contains information on project watersheds. It consists of the following three elements:

WATS.maps - Watershed Maps  
WATS.POLYS - Watershed Polygon Coordinates  
WATS.DAREAS - Drainage Area Characteristics

This information supplements the location descriptors contained in the LISTS files. Each element is described below.

27. A set of watershed maps has been compiled from the USGS hydrologic unit maps<sup>8</sup>, EPA National Eutrophication Survey Working Papers<sup>9</sup>, and a report on CE projects in the New England Division<sup>11</sup>. The maps are labeled with descriptive data contained in the LISTS.CPL file and stored in a loose-leaf notebook. Hydrologic unit maps, used most extensively, are on a scale of 1:500,000. An example is given in Figure 3. In some cases, projects have been built after map publication and only the watersheds are shown.

28. WATS.POLYS contains the latitude/longitude coordinates of polygons which contain projects and their watersheds. These coordinates have been used to identify water quality monitoring stations in STORET (see Part IX). Each record contains up to five coordinate pairs and is referenced by district and project codes. Coordinates have been estimated from watershed maps contained in EPA National Eutrophication Survey reports<sup>9</sup>. The 108 projects which were sampled under that program are represented in WATS.POLYS file.

29. WATS.DAREAS contains additional descriptive information on project watersheds in the format given in Table 10. Each record is referenced by district, project, and data source codes. Table 11 lists the elements of the file along with corresponding data sources. Some discrepancies among multiple data sources for the same project and characteristic remain in the file, particularly in drainage areas and mean flows. These could be resolved through verification of the file at the district level. An inventory of the file contents by division is given in Table 12. Inventories by project and district are given in Appendix A.

## PART VII: RESER - RESERVOIR CHARACTERISTICS

30. The fourth major file grouping, RESER, contains detailed information on reservoir characteristics. It consists of the following four elements:

RESER.MORPHO - Project Morphometry  
RESER.desc - Verbal Project Descriptions  
RESER.broch - CE Recreational Brochures  
RESER.COM - Comments

Each of these elements is described below.

31. The fluctuating pool levels characteristic of many reservoirs necessitates the compilation of morphometric data which are referenced to pool elevations. Volume and surface area variations with elevation are required for estimation of volume-averaged water quality conditions, given measurements made at specific depths. Seasonal variations in reservoir volume and discharge induce variations in mean depth and hydraulic residence time which may, in turn, influence the response of trophic state indicators to nutrient loading. Thus, detailed morphometric information is an essential component of the data base for eutrophication modelling and for other general uses.

32. The record format and contents of the RESER.MORPHO file are described in Table 13. Each record is referenced by district, project, elevation, and data source code. In addition to area, volume, length, width, and shoreline length data, the file contains a series of pool and outlet codes, as listed in Table 4. These codes provide supplementary descriptive information on pool allocations for various uses, ranges of operating levels, and locations and types of principal outlets.

33. The RESER.MORPHO file was initially based upon data extracted from project design memoranda. The other principal data sources include: (1) a report by Leidy and Jenkins<sup>5</sup>; (2) USGS water resources data reports, by state and year<sup>13</sup>; (3) sedimentation survey sheets<sup>12</sup>; and (4) district and division offices. Information compiled from these sources has been coded and sorted by project and elevation. Initial screening was done to identify and correct, where possible, any

obvious errors, such as decreasing area or volume with increasing elevation within a given project. There were sufficient inconsistencies among the various data sources for many projects to warrant independent verification of the file. Accordingly, the file was distributed to the districts through WES and additions and corrections were made based upon district responses. Final editing was done to eliminate most of the redundancies in the file due to multiple data sources for the same project and elevation. A current data inventory by division is given in Table 14. Inventories by district and project are given in Appendix A.

34. RESER.desc consists of a collection of verbal project descriptions copied from USGS water resources data reports published annually by state<sup>13</sup>. The descriptions are referenced by district and project codes and assembled in a loose-leaf notebook. These descriptions summarize hydrologic monitoring activities by the USGS, along with important project characteristics and purposes. The file currently contains entries for 260 out of 299 projects in the central project list.

35. RESER.broch is a collection of brochures published by CE district and division offices as guides to recreation in specific projects. These usually contain detailed project maps which are useful for locating monitoring stations. Project purposes and characteristics are also summarized. Each folder is referenced by district and project number and stored in a hanging file. Currently, the file contains information from eight districts: Pittsburg, Huntington, Louisville, Nashville, Vicksburg, Tulsa, Forth Worth, and Sacramento.

36. The RESER.COM file contains miscellaneous descriptive information on various projects. This file has been designed to hold data or comments which do not conform to other file formats. Each record is 80 characters long and is referenced by district and project codes. A listing of the current version of this file is given Table 15.

01157 Mad River dam now under control of State of Connecticut  
01165 Connected to Hopkinton (01167) at high water  
01167 Connected to Everett (01165) at high water  
07232 Project transferred to Wilmington District (06)  
26363 Sediment survey refers to Old Waco  
28408 No permanent pool  
30214 2 Separate lakes (W. twin/E. twin) below elevation 1342  
30333 Project never reached full pool  
33298 Re-regulating dam for Green Peter (33299)  
33305 Re-regulating dam for Detroit (33293)  
34048 Sediment survey refers to Old Don Pedro  
34051 Sediment survey refers to Old Exchequer

## PART VIII: HYDRO - HYDROLOGY FILES

37. The fifth file group, HYDRO, contains detailed hydrologic data, organized in the following files:

HYDRO.KEY	- Station Key
HYDRO.DAILY	- Daily Values
HYDRO.MONTHLY	- Monthly Summaries
HYDRO.YEARLY	- Yearly Summaries
HYDRO.SUM	- Grand Summaries

This information has been compiled to provide bases for nutrient budget calculations, estimating pool hydraulic residence times (as influenced by reservoir elevation and discharge), and depth-averaging of water quality observations (as influenced by reservoir morphometry and pool level). Because of the stringent water quality sampling requirements for estimation of nutrient budgets, streamflow data required for such calculations have been compiled only for those projects and years sampled by the EPA National Eutrophication Survey. Attempts have been made, however, to compile reservoir discharge and elevation/contents data from all projects for 1965 to date using three data sources: USGS/WATSTORE<sup>14</sup>, the EPA National Eutrophication Survey<sup>15</sup>, and sedimentation survey sheets<sup>12</sup>. The HYDRO.KEY file describes 1307 stations from all three data sources in the format depicted in Table 16.

38. The first data source includes USGS stations monitoring reservoir elevation/contents or streamflow at or below reservoir discharge points. These stations have been identified using the Master Water Data Index of the USGS National Water Data Exchange<sup>16</sup> and USGS water resources data reports by state and year<sup>13</sup>. Daily values have been retrieved through STORET<sup>3</sup> for the period from 1965 to the most recent available as of February, 1980. Only those stations with daily values entered in WATSTORE are included.

39. The EPA National Eutrophication Survey<sup>4</sup>, which sampled 108 CE projects, assembled a hydrologic data base compatible with its water quality sampling network for use in nutrient budget computations. It includes streamflow estimates for upstream and downstream tributaries.

For each station, flows are estimated on three time scales: daily (only for the days on which water quality samples were taken), monthly (only for the months in which water quality samples were taken), and normalized monthly (normal flow for each month). This information has been retrieved from a tape provided by the EPA Corvallis laboratory<sup>15</sup>. Monthly and normalized monthly flows have been stored in the HYDRO.MONTHLY file. Because they only refer to water quality sampling dates, daily flows have been stored along with the water quality data in the WQ.OBS file.

40. The third source of hydrologic data, sedimentation survey sheets<sup>12</sup>, has provided annual estimates of reservoir total inflow, minimum elevation, and maximum elevation, typically for 10 water years in most of the 84 projects for which sedimentation survey sheets have been located. This information has been stored in the HYDRO.YEARLY file.

41. The formats of the DAILY, MONTHLY, YEARLY, and SUM hydrology files are listed in Tables 17 through 20, respectively. HYDRO.DAILY, which contains data from USGS/WATSTORE stations only, is in the WATSTORE format. It is linked to the project list through the sequence number stored in the HYDRO.KEY file. The other hydrology files contain direct references to districts and projects. In retrieving daily values, all parameter codes recorded at each station were included. Thus, the daily file, and the monthly, yearly, and grand summaries generated from it, contain some water quality information monitored by the USGS on a daily basis (e.g., temperature, conductivity, suspended solids). Parameter codes and coverage are indicated in Table 5.

42. Monthly variations in reservoir discharge and elevation are needed in order to provide bases for calculating pool hydraulic residence times and volume-averaged water quality conditions on a seasonal basis. Table 21 presents an inventory of reservoir discharge, elevation, and contents data monitored at USGS stations and contained in the HYDRO.MONTHLY file. Table 21 is organized by division. Corresponding inventories by reservoir and district are contained in Appendix A. Since the monthly hydrologic summary has been generated from the daily values file, these inventories also reflect daily data holdings.

43. The files contain reservoir discharge data for 245 out of the 299 projects in the central project list. Elevation and contents data are included for 44 and 108 projects, respectively. Regional deficiencies in elevation or contents data are particularly evident for the New England, North Atlantic, South Atlantic, Ohio River, and Missouri River Divisions. These deficiencies need to be corrected, probably using district-level information sources, in order to provide a basis for model evaluations under Phase II of this project.

PART IX: WQ - WATER QUALITY FILES

Introduction

44. The sixth group of files, WQ, contains water quality information for CE projects. It is organized as follows:

WQ.KEY	- Station Key
WQ.DESTAT	- Detailed Station Descriptions
WQ.OBS	- Observations
WQ.SUM	- Data Summary by Station and Parameter
WQ.maps	- Station Maps

Three sources of water quality data have been used: (1) EPA's STORET system<sup>3</sup>; (2) the INFONET<sup>17</sup> system used by the Ohio River Division of the Corps of Engineers; and (3) miscellaneous survey data for specific projects. The numbers of stations and observations obtained from each source are listed in Table 22. The use of these sources and resulting file structures and contents are described in the following sections.

STORET Data Acquisition and Processing

45. As in Table 22, STORET is the primary source of water quality information. The following sources have been used to identify station codes and to associate them with specific CE projects:

- a. the Master Water Data Index (MWDI) maintained by the National Water Data Exchange of the USGS<sup>16</sup>.
- b. the USGS Catalogue of Information on Water Data<sup>18,19</sup>.
- c. a list of stations included in the National Stream Quality Accounting Network (NASQAN) maintained by the USGS<sup>20</sup>.
- d. the EPA National Eutrophication Survey Working Papers<sup>9</sup>. and
- e. direct station identification retrievals from STORET using a latitude/longitude search technique.

These sources are described below in the order used.

Table 22  
Inventory of Water Quality Data by Source

<u>Agency</u>	<u>Stations</u>	<u>Sample Dates</u>	<u>Observations</u>
STORET - EPA/NES	1,637	16,119	181,173
STORET - USGS	655	35,326	592,853
STORET - CE	470	34,890	322,337
STORET - States	541	18,243	235,894
STORET - Other	357	8,078	154,266
INFONET - ORD	763	16,995	534,412
Miscellaneous	28	170	2,259
<b>TOTAL</b>	<b>4,451</b>	<b>129,821</b>	<b>2,023,194</b>

46. The Master Water Data Index (MWDI) documents water quality and quantity monitoring activities by various local, state, and federal agencies throughout the U. S. and contains information on site location, agency, dates, types of measurements, and data storage media. It does not contain measurements, but serves as a means of locating them. The MWDI registers all stations in the EPA STORET and USGS WATSTORE systems, in addition to information on monitoring activities by agencies which do not participate in other federal data banks. Thus, this file represents the most comprehensive one available for identifying monitoring sites and locating data. An initial list of monitoring stations associated with specific projects was derived by applying a latitude/longitude search technique to two large station files acquired on tape from the National Water Data Exchange. One contained all stations in the U. S. monitored by the Corps of Engineers, and the other contained all lake or reservoir stations monitored by any agency in the U. S. The station/project matching derived from this search was verified manually by checking station location descriptions and consulting maps, when needed.

47. The station listings derived from the MWDI did not contain stations monitored by non-CE agencies on tributary streams. The second and third sources listed above provided additional tributary stations operated primarily by the USGS. NASQAN<sup>20</sup> stations are particularly data-rich, having been operated by monthly frequencies since 1975 with a broad water quality parameter coverage. Forty-nine such stations have been located in or directly below the watersheds of projects in the central project list.

48. The STORET station list also includes all stations operated by the EPA National Eutrophication Survey in 108 CE projects. These stations include upstream tributaries, point sources, reservoir stations, and reservoir discharge stations. Nutrient loading calculations for these projects will provide a basis for the testing loading models in Phase II.

49. Finally, a series of station identification retrievals were done directly in STORET using a search technique based upon the latitude/longitude polygons contained in the WATS.POLYS file. Because of cost and time considerations, this technique was applied only to projects which were in one of two categories: (1) sampled by the EPA National Eutrophication Survey (since these will be the primary focus of Phase II modelling efforts); or (2) without water quality data derived from other station searching techniques. An extracting option available in STORET was also used to identify only stations for which total phosphorus measurements were available.

50. Experience with these alternative station searching techniques indicates that no one method is completely satisfactory. Each relies upon the accuracy of the station characteristics and coordinates entered in the STORET file. Polygon search techniques often retrieve extraneous stations or miss relevant stations because of inaccurate latitude/longitude entries in the STORET station file. Similarly, retrievals which depend upon station types (e.g., "stream" vs. "lake") will miss stations which have been inaccurately classified. For example, many stations located in reservoir pools (based upon location descriptions and/or coordinates) were classified as "stream" stations in STORET and MWDI. The variety of methods employed to identify stations has helped to provide reasonable project coverage. All station/project matchings in the final STORET station list have been checked manually with reference to verbal station location descriptions and maps.

51. Preliminary STORET retrievals have been used to screen out sites with little or no relevant information and to verify station codes. Results have been obtained in the STORET Inventory format, which lists station descriptions and statistical summaries of water quality components monitored. Based upon these inventories, most stations with only one sampling date have been eliminated from the station list.

52. Following the screening procedure, a second series of STORET retrievals has been used to obtain copies of the data on tape for all observations made after 1964. The most comprehensive retrieval format

available from STORET has been used. This format, termed "MORE=5", provides complete station descriptions along with observations of up to 50 different water quality variables at each station.

53. A total of 100 variables have been selected for inclusion in the data base, as listed in Table 5. This necessitated two retrievals for each station. The selection of variables is based upon the objectives of the project and upon the results of the preliminary station inventories, which gave initial indications of data availability as a function of parameter code. The list contains some redundancies due to multiple ways of expressing various types of measurements (e.g., temperature as degrees F or degrees C or phosphorus as P or PO<sub>4</sub>). Conversion routines have been used to eliminate these redundancies in tape processing.

54. In a final step, the STORET tapes have been processed to generate one file containing station descriptions (WQ.DESTAT) and another containing water quality observations (WQ.OBS). This involved several sort/merge steps to combine data from the individual STORET tapes in a sequenced form. Overall, STORET has provided 1,486,523 observations at 3,660 stations.

#### INFONET Data Acquisition and Processing

55. The INFONET<sup>17</sup> system used by the Ohio River Division to manage water quality data has been accessed as a second source of information. Five tapes have been obtained from ORD, one containing station descriptions and the other four containing water quality observations for each of the four ORD districts (Pittsburgh, Huntington, Nashville, and Louisville). Because the organization and formats of the INFONET tapes are different from those obtained from STORET, a different set of programs has been written and employed to extract the data and process it into a form suitable for merging with output from the STORET tape processing.

56. A systematic procedure has been used in extracting data from the ORD tapes. In the first step, stations of interest have been selected

from the ORD station tape based upon ORD project identification codes and used to generate a station description file keyed to members of the central project list. A list of primary and secondary ORD station codes has been extracted from the station description tape. In the final step, the station code and parameter code files have been used to extract relevant observations from the ORD data tapes. This process has been repeated for each district and the resulting files have been merged. A total of 763 stations and 534,412 observations have been derived from this data source.

#### Miscellaneous Data Acquisition and Processing

57. Water quality data acquired from STORET and INFONET have been supplemented with miscellaneous data which has been manually coded and entered directly into the water quality files. This has been done to improve the regional coverage of the water quality data base. This relatively time-consuming approach has been limited to two sources: (1) survey data obtained from Baltimore District<sup>21</sup> for Almond, Whitney Point, and Alvin R. Bush Reservoirs; and (2) survey data obtained from the North Central Division<sup>22</sup> for Eau Galle Reservoir and Lac Qui Parle.

58. Water quality data and station descriptions from these sources have been coded at WES. Keypunching and verification have been done at MIT. The resulting files containing 28 stations and 2259 observations have been merged with data from STORET and INFONET in the formats described below.

#### WQ File Structures

59. The water quality data base consists of four files (WQ.KEY, WQ.DESTAT, WQ.OBS, WQ.SUM) and a set of station maps (WQ.maps). The formats of the four files are given in Tables 23 through 26, respectively. The structure and contents of each are discussed below.

60. WQ.KEY (Table 23) contains station source and location descriptors and accounting information on the amount of data in the WQ.OBS file, including the number of observations, number of sampling dates, date range, and depth range. Station descriptors have been derived from the WQ.DESTAT file, and accounting information from the WQ.OBS file. Each station has been given a unique, 8-digit identifying code. The first two digits represent CE district (Table 1) and the next three represent CE project (Table 8). The last three contain a code which is unique within each project. The following conventions have been used in assigning the last three digits of the station code:

001 - 100	STORET stations retrieved in March of 1979
101 - 200	STORET stations retrieved in March of 1980
301 - 400	EPA National Eutrophication Survey stations
501 - 600	INFONET stations (Ohio River Division)
801 - 900	stations entered manually

Station numbers have been assigned sequentially within each category and project, after sorting the stations by STORET agency and STORET station codes. The station coding scheme permits sorting and analysis by station, district, project, station, and/or data source. The WQ.KEY file contains 4451 records (one per station), sorted by the 8-digit station code.

61. WQ.DESTAT contains detailed information on station location and data source. As shown in Table 24, it contains four record types. The fourth type is repetitive and contains up to 15 lines of detailed descriptive text on each station. WQ.DESTAT contains about 31,000 records, sorted by the first ten digits of each record (station code/record sequence number).

62. WQ.OBS (Table 25) contains water quality observations. Each record is identified by station, date, time, depth, and parameter code. Standard STORET remark codes identify measurements which are less than or greater than indicated values or duplicate values. The last part of each record contains composite sample information. WQ.OBS, which contains 2,023,194 records, sorted by the first 24 columns (station/date/time/depth/parameter), is stored on tape (sequential access only).

63. WQ.SUM (Table 26) contains a water quality data summary by station and parameter, derived from analysis of the WQ.OBS file. Statistics include date range, depth range, value range, mean, standard deviation, and value percentiles (25%, 50%, and 75%). Summary statistics are derived from the first 1000 observations for each station/parameter combination. Each record represents one station/parameter combination and the file contains about 75,000 records sorted by station and parameter codes.

64. To provide direct access to water quality station descriptions and data summaries, the contents of the WQ.DESTAT and WQ.SUM file have been produced in microfiche form. Frame format is illustrated in Table 27. The heading of each frame contains the district, project, station, and station type codes and names. Station descriptions are entered from the WQ.DESTAT file. The data summary by parameter follows. Frames are sorted by district, project, and station codes. A new fiche card is begun with each district. Card labels indicate the district and project described in the first frame. The last frame of each card contains an index which lists the project, station, and associated frame coordinates.

65. WQ.maps is a collection of station maps (one per project) which have been produced on a Calcomp line plotter using information in the WQ.KEY file. An example is given in Figure 4 which can be compared with the watershed map in Figure 3. Stations are located based upon latitude/longitude coordinates. Different plot symbols are used to identify station types. Only stations with more than 10 observations are plotted. Adjustments in horizontal and vertical scales are made for each map so that a linear distance scale is preserved and the map fits within an 8.5 x 11 inch area. A scale factor in miles per inch is derived from the LISTS.CPL file and plotted with a triangle. These maps are useful for identifying station locations and for refining the station type codes. They are subject, however, to errors in the station coordinates derived from STORET or INFONET. Based upon the maps and station

descriptions, some editing of obvious coding errors in station coordinates has been possible.

#### WQ Data Inventories

66. Table 28 presents an inventory of water quality data by station type and division. Corresponding inventories by project and district are given in Appendix A. Overall, 271 out of 299 projects are represented in the water quality files. Remaining regional deficiencies include St. Paul District (6 out of 13 projects), Portland District (9 out of 17 projects), and Los Angeles District (0 out of 2 projects).

67. An inventory by station type and parameter code is given in Table 29. As expected, temperature, pH, and oxygen are the most frequently represented parameter codes in the file. No data were located for one code (09 -- average daily spillway flow).

68. Phosphorus, chlorophyll-a, and Secchi depth data are particularly relevant to assessing eutrophication problems and therefore to Phase II modelling efforts. Table 30 presents an inventory of these measurements made at pool stations (type codes 2, 4, or 5) by division. Corresponding inventories by project and district are given in Appendix A. Out of 299 projects in the central project list, total phosphorus data have been located for 211, chlorophyll-a data for 132, and Secchi depth data for 171. Some regional deficiencies in total phosphorus data are evident particularly in the New England Division (12 out of 22 projects), North Atlantic Division (6 out of 15 projects), North Central Division (6 out of 16 projects), and North Pacific Division (6 out of 27 projects). These are also reflected in the chlorophyll-a and Secchi depth inventories. These inventories indicate that the data base will not be sufficient to assess the trophic state of all CE projects with appreciable pools. The complete coverage for roughly 130 projects indicates, however, that the data base should be generally sufficient for model testing purposes, the primary objective of Phase II. Regional testing of models should also be possible, with a few exceptions (e.g.,

the lack of chlorophyll-a or Secchi depth data for projects in New England).

69. The EPA National Eutrophication Survey is a primary source of data for testing nutrient loading models and relationships among within-pool measures of trophic state. An inventory of data holdings by agency, station type, and parameter code is given in Table 31. Two agency groupings are used: "EPA", representing the National Eutrophication Survey; and "OTHER", representing all other agencies and monitoring programs. Station types include tributary (type code 1), discharges (type code 3), and pool (type codes 2, 4, and 5). The parameter list includes a variety of nutrient, biological, chemical, and optical characteristics pertinent to eutrophication analysis. Within each category, the numbers of observations, sampling dates, stations, projects, and districts are indicated, along with the total period of record in station-months. Including data from agencies other than the EPA/NES has more than doubled the total numbers of observations of most parameters and provided additional useful measurements for some projects, such as algal cell numbers and volumes, turbidity, and suspended solids. At pool stations, non-EPA agencies provide more chlorophyll-a observations (2036 vs. 1499) concentrated in fewer projects (43 vs. 108). These and other statistics in Table 31 reflect the relative intensities of agency monitoring efforts--many of the non-EPA programs are more intensive and extensive temporally than the three-date, one-growing-season program employed by the EPA/NES.

70. Based upon data inventories in Appendix A, some projects for which non-EPA data monitoring of trophic state indicators has been partic    ly intense include the following:

06-372	John H. Kerr
15-399	Eau Galle
16-311	East Branch Clarion River
18-093	Monroe
18-120	Barren River
19-340	J. Percy Priest
26-359	Sam Rayburn
29-111	Pomona
32-204	Kookanusa

Thus, it will not be necessary in Phase II to rely exclusively upon data from the EPA/NES for assessing relationships among within-pool measures of trophic state. The stringent water quality and flow sampling program requirements required for estimation of nutrient budgets and time limitations of this project suggest, however, that EPA/NES data be used exclusively for evaluating nutrient loading models.

PART X: SED - SEDIMENTATION DATA

71. The seventh major file group describes sedimentation characteristics of CE reservoirs. It contains the following elements:

SED.sheets - Sedimentation Survey Sheets  
SED.RATES - Sedimentation Rate File

This information has been derived from a collection of sediment survey data for U. S. reservoirs compiled in 1975 by the Agricultural Research Service of the U. S. Department of Agriculture<sup>10,12</sup>. A total of 84 CE projects in the central project list were included in that compilation. These are identified by the sedimentation survey key in the LISTS.CPL file (Table 8).

72. SED.sheets consists of a collection of the most recent sedimentation survey sheets contained in the appendix to the U. S. Department of Agriculture (USDA) compilation<sup>12</sup>. These sheets contain detailed information on project location, morphometry, hydrology, as well as sedimentation. An example is given in Table 32. Sheets have been assembled in a loose-leaf notebook, identified, and arranged by district and project code.

73. SED.RATES is a file containing the most recent estimates of sedimentation rates for each of the 84 projects located in the USDA compilation<sup>10</sup>. The format of this file is given in Table 33. Many of the sedimentation rate measurements antedate the water quality file. For 45 projects, the most recent survey data available were taken during or before 1965. Rate estimates for some projects, however, will be useful for testing relationships between sedimentation rate and nutrient trapping efficiency during Phase II of this study.

## PART XI: NES - EPA NATIONAL EUTROPHICATION SURVEY DATA

74. The eighth file group consists of data and reports obtained from the EPA National Eutrophication Survey<sup>4,9</sup>, exclusive of the water quality, hydrologic, and drainage area data described in previous sections. It consists of the following elements:

NES.reports - EPA/NES Working Papers  
NES.COMP - Compendium of Lake and Reservoir Data  
NES.SUM - Compendium Summary

This file group contains information on 108 CE projects as well as the other 704 lakes and reservoirs which were sampled by the EPA/NES throughout the U. S. Besides providing detailed information on point-source nutrient loadings to CE projects needed for nutrient budget estimation in Phase II, it provides a basis for comparisons of lakes and reservoirs with respect to morphometric, hydrologic, and nutrient loading response characteristics. Such comparisons, in turn, can provide means of interpreting the performance of lake nutrient loading models in reservoirs.

75. During 1972-75, the EPA conducted a systematic survey of 812 lakes and reservoirs in the U. S. The original objective of the National Eutrophication Survey was to develop a data base for assessing the impacts of point-source nutrient discharges on the trophic conditions of lakes and reservoirs. The NES produced a series of working papers<sup>9</sup> summarizing and interpreting the results for each impoundment or lake monitored. Results have also been summarized in a compendium format and published in four volumes<sup>23</sup>.

76. NES.reports consists of the collection of working papers describing NES surveys and results in each of 108 CE projects. Each report has been referenced to the data base by district and reservoir code. Maps extracted from the reports have been included in the WATS.maps file.

77. NES.COMP is a computer file containing a nationwide summary of NES data for 775 lakes and reservoirs, obtained from the Corvallis laboratory of the EPA<sup>4</sup>. A sample printout of data from the file is given in Table 34. Similar printouts have been produced for all CE

projects in the compendium file and arranged in a notebook by district and project code. The compendium contains data for 106 out of 108 CE projects sampled by the EPA/NES.

78. NES.SUM is a summary of the NES.COMP file, with a few modifications. The format of the summary file (Table 35) is more convenient for input to statistical analysis programs, since one record is used for each lake or reservoir. A number of missing latitude and longitude coordinates have been added, based upon estimates derived from USGS Hydrologic Unit Maps<sup>6</sup>. Each lake or reservoir has also been referenced by CE division to provide a basis for regional contrasts of lake and reservoir characteristics.

79. A few simple analyses have been done to provide descriptions of types and amounts of data contained in the NES.SUM file. The regional distribution of lakes and reservoirs described in the file is depicted in Figure 5. A breakdown of impoundment numbers as a function of trophic state, impoundment type, and CE division is given in Table 36. The numbers of CE projects are listed as a function of division and trophic state in Table 37.

80. The results of preliminary lake/reservoir comparisons which have been made using data from the NES compendium tape are summarized in Table 38. Three groups of impoundments have been compared: natural lakes (N=310); non-CE reservoirs (N=359); and CE reservoirs (N=106). The stratification of thirty-six original and composite variables across these groups has been studied using the BMDP-77 computer program<sup>1</sup>. Within-group means and Analysis of Variance (ANOVA) statistics are listed in Table 38. Detailed results with histograms are presented in a previous report<sup>24</sup>.

81. While the scope of this report precludes detailed interpretations of the data, a few comments on these results seem appropriate:

- a. At the 95% significance level, differences across groups are evident in all cases except longitude, conductivity, phosphorus retention coefficient, nitrogen retention coefficient, and the second Vollenweider phosphorus loading statistic<sup>25</sup>.

- b. Strongest differences across groups are apparent for drainage area ( $F=77.5$ ), drainage area/surface area ( $F=73.6$ ), outflow rate ( $F=60.7$ ), and drainage area/maximum depth ( $F=53.4$ ).
- c. Reservoirs have higher potential phosphorus concentrations, based upon phosphorus loading and the Vollenweider statistics, but lower observed phosphorus and chlorophyll-a concentrations than natural lakes. This is an indication that the Vollenweider statistics may give biased predictions in reservoirs (i.e., over-predict loading impact).
- d. Reservoirs have less transparency, despite less chlorophyll-a. This is probably an effect of mineral turbidity in reservoirs.
- e. N/P loading ratios are somewhat lower for reservoirs than for natural lakes; the reverse is true, however, for inorganic N/dissolved P ratios measured during the summer within the impoundments.
- f. The composite statistic (Secchi depth/mean depth) is strongly stratified across groups ( $F=44.8$ ). Assuming that the depth of the photic zone is roughly twice the Secchi depth, the means in Table 38 indicate that typically 62% of the volume of lakes is available for photosynthesis, compared with 30% in the case of CE reservoirs. Reservoirs probably have greater shoreline development, however, and may be more influenced by photosynthetic processes occurring in littoral zones.
- g. While a 4-degree difference is evident in the average latitude of CE reservoirs as compared with lakes, a detailed look at Figure 5 reveals that the distribution of NES lakes is bimodal, with clusters in the North (primarily Minnesota, Wisconsin, Michigan, and Maine) and in the extreme South (Florida). The maximum reservoir density occurs between these extremes.

Because of the strong regionality of the lake vs. reservoir distributions evident in Figure 5, it is difficult to separate the effects of impoundment type from those of region with analyses of the type described above. Thus, in future, more complete analyses, it will be important to control for regional differences by comparing subsets of lakes and reservoirs within defined regions.

PART XII: NUMERICAL CHARACTERIZATION OF RESERVOIR HYPSOGRAPHIC CURVES

Introduction

82. Estimates of reservoir volume and area variations with elevation are required for computing volume-averaged concentrations and pool hydraulic residence times. This information is generally available in the form of a table which lists area at and volume below specific elevations. Morphometry tables have been compiled for most of the 303 CE projects in the data base. This paper describes numerical investigations of these tables, specifically covering the relative accuracies of various curve-fitting and interpolation techniques. Results will be used to design methods for summarizing, storing, and applying morphometric information in other phases of the project. Results are also relevant to other aspects of reservoir management, specifically including the estimation of reservoir volumes and sedimentation rates from range survey or contour area data.

83. This study has been performed prior to completion of the project morphometry file. A subset of data has been selected which covers 147 projects, each with at least five listed elevations and without obvious errors (such as decreasing areas or volumes with increasing elevation). A total of 1285 elevation/area/volume data points have been compiled for these 147 projects from various sources. Results of this study are summarized below. Details can be found in a working paper submitted as a progress report under this contract<sup>26</sup>.

Approach

84. The objective is to design and evaluate methods for estimating area and volume at any elevation, given information available for specific elevations. Methods can generally be classified as curve-fitting or interpolating. Accuracies of these methods can be assessed by comparing observations and predictions of the following:

- a.  $\hat{V}(V)$  = volume estimated from volume/elevation points
- b.  $\hat{A}(V)$  = area estimated from volume/elevation points
- c.  $\hat{A}(A)$  = area estimated from area/elevation points
- d.  $\hat{\Delta V}(A)$  = incremental volume estimated from area/elevation points

Statistics a and c are simple curve-fitting or interpolating problems.

Statistic b involves differentiation of the volume curve to estimate area:

$$\hat{A}(V) = \frac{\partial V}{\partial Z} \quad (1)$$

where

$Z$  is the total depth, ft

Statistic d involves integration of the area curve between specific depth limits ( $Z_1$  and  $Z_2$ ) to estimate incremental volume:

$$\hat{\Delta V}(A) = \int_{Z_1}^{Z_2} AdZ \quad (2)$$

85. In testing each method, a jackknife procedure<sup>27</sup> has been used to estimate the above statistics for internal elevation points (i.e., tests are not made for the top and bottom listed elevations in each project, although these elevations are used in the fitting or interpolating process). In applying the jackknife, information from the point being tested is not used in estimating the parameters of the predictive function. For instance, estimates of area or volume at the second listed elevation are derived exclusively from information in the first and third through last listed elevations.

86. Reported values and predictions are compared using the following error statistic:

$$D = \log_e \left[ \frac{2Y}{Y + \hat{Y}} \right] \quad (3)$$

where

$Y$  = reported value ( $V$ ,  $A$ , or  $\Delta V$ )

$\hat{Y}$  = estimated value

$D$  = error statistic

For errors of the magnitude studied here, the value of D approaches the difference between the reported and predicted values, expressed as a fraction of their average. In most cases, the D statistic seems to have reasonably symmetric error distributions. For each of the four types of area/volume comparisons, estimates of bias and standard error in D have been derived for a variety of predictive methods, as described below.

#### Curve-Fitting Schemes

87. A single-term power function has some useful properties for fitting these types of curves and is the simplest of the methods evaluated:

$$\hat{V} = c_v Z^{b_v} \quad (4)$$

$$\hat{A} = c_a Z^{b_a} \quad (5)$$

$$Z = E - E_o \quad (6)$$

where

$c_v$ ,  $c_a$ ,  $b_v$ ,  $b_a$  = empirical parameters

Z = total depth (ft)

E = elevation (ft, msl)

$E_o$  = elevation at  $V=A=0$  (ft, msl)

Model parameters can be estimated using linear regression by transforming V, A, and Z values to logarithms. The following equalities should hold if the model is valid for a particular reservoir:

$$\frac{\partial V}{\partial Z} = b_v c_v Z^{b_v - 1} = A \quad (7)$$

$$\therefore c_a = b_v c_v \quad (8)$$

$$b_a = b_v - 1 \quad (9)$$

Equations (8) and (9) can be used to test the consistency of the volume and area curves. The slopes of volume and area vs. total depth on a

log/log plot should differ by 1.0. Dividing equation (4) by equation (5) yields the following:

$$\left(\frac{\hat{V}}{A}\right) = \frac{c_v}{c_a} z^{b_v - b_a} = b_v z \quad (10)$$

If the basic model holds, the ratio of volume to area (or mean depth) should be proportional to the total depth. Thus, the model can be tested through regression analysis of the following equation:

$$\left(\frac{\hat{V}}{A}\right) = c_z z^{b_z} \quad (11)$$

A t-test can be applied to the mean and standard error  $b_z$  within each project to determine whether the estimate is significantly different from 1.0.

88. In testing the power function model, the parameters in equations (4), (5), and (11) have been estimated for each of 147 reservoirs. The statistical distributions of the optimal slope parameters ( $b_v$ ,  $b_a$ ,  $b_z$ ) are shown in Figure 6 on log-normal probability scales. Median values are 2.97, 1.97, and 0.97, respectively. Thus, in the "typical" reservoir, volume and area increase approximately as the cube and square of total depth, respectively. This corresponds to the solid geometry of an inverted cone or pyramid. About 10% of the projects have  $b_v$  values exceeding 4 and 4% have  $b_v$  values less than 2. The parameters  $b_a$  and  $b_v$  contain roughly the same information as the statistically-defined "lake form" proposed by Hakanson<sup>28</sup>.

89. Based upon t-tests, the  $b_z$  parameter differs significantly ( $p=.05$ ) from 1.0 in about 35% of the projects. This means that the single-term power function model fits about two thirds of the projects. In the remaining one third, the slope parameters  $b_v$  and  $b_a$  are inconsistent and/or variable with depth.

90. Table 39 lists error statistics for this model. Estimates of the first ( $\hat{V}(V)$ ) and third ( $\hat{A}(A)$ ) statistics are derived directly from equations (4) and (5), respectively. Areas are estimated from volume

Table 39  
Evaluation of the Power Function Model

Statistic	Gross* Standard Error	Median** Standard Error
$\hat{V}(V)$	.097	.062
$\hat{A}(V)$	.115	.081
$\hat{A}(A)$	.097	.062
$\Delta\hat{V}(A)$	.177	.081

\* estimated from mean-squared D value (equation (3))

\*\* median of within-project mean-squared D values

curves according to equation (7). Changes in volume within various strata are estimated from area curves according to:

$$\Delta \hat{V}(A) = \int_{z_1}^{z_2} A dz = \int_{z_1}^{z_2} c_a z^{b_a} dz \quad (12)$$

$$= \frac{\hat{A}_2 z_2 - \hat{A}_1 z_1}{b_a + 1} \quad (13)$$

Standard errors of D range from .097 ( $\hat{V}(V)$ ) to .177 ( $\Delta \hat{V}(A)$ ). The higher standard error of  $\Delta V(A)$  could be related to the fact that it is an incremental value which is more subject to measurement error on a percentage basis than is total volume or area. A D standard error of .097 corresponds roughly to a standard error of 10%, or to 95% confidence limits of  $\pm 20\%$  in an estimated area or volume. The differences between the gross standard error and the median, within-project standard error reflects the skewness of the error distribution across projects, i.e., the model seems to fit some projects considerably better than others, as indicated by the  $b_z$  distribution.

91. In order to improve upon the above model, variations in the slope parameters  $b_v$  and  $b_a$  with depth must be accounted for. The simplest way of doing this is to include higher-order terms in the regression equations:

$$\hat{V}^* = \sum_{i=0}^m c_i z^{*i} \quad (14)$$

$$\hat{A}^* = \sum_{i=0}^m d_i z^{*i} \quad (15)$$

where

$c_i, d_i$  = empirical coefficients ( $i=0, m$ )

\* = superscript denoting  $\log_{10}$  transformation

$m$  = maximum degree of polynomial

The error distributions of these functions have been evaluated for maximum degrees ranging from 1 to 5. For  $m=1$ , the scheme is equivalent

to the single-term power function model discussed above. For comparative purposes, linear polynomial functions have also been tested:

$$\hat{V} = \sum_{i=0}^m c_i z^i \quad (16)$$

$$\hat{A} = \sum_{i=0}^m d_i z^i \quad (17)$$

For each reservoir, the maximum degree of the polynomial has been limited to the minimum of  $m$  and the number of elevations in the table minus two.

92. The error statistics in Table 40 indicate that logarithmic polynomials are preferable to linear ones according to most criteria. Log transformation tends to linearize the relationships and renders them easier to fit with low-order polynomial terms. Some reduction in error is achieved by including quadratic and cubic terms in depth. Addition of fourth- and fifth-order terms, however, tends to increase estimation error, presumably because higher-order polynomials can have local minima and/or maxima between the fitted points. These are artifacts of the fitting process which can cause large estimation errors between the fitted points. Cubic polynomials apparently have about the best combination of flexibility and smoothness for these purposes and data densities.

#### Interpolation Schemes

93. Interpolation methods can be used as alternatives to the curve-fitting techniques described above. Interpolation essentially involves fitting different curves to different sections of each volume/area/elevation table. A variety of interpolation methods have been tested on the same data set used above<sup>26</sup>. These involve different transformations of the volume and area points, including inverse power functions (first through fifth order) and logarithmic. Of the methods tested, one involving logarithmic transformations of volume, area, and total depth points has been shown to have the lowest error statistics<sup>26</sup>. The errors, however, are essentially equivalent to the error

Table 40  
Evaluation of Polynomial Functions

Transformation	Maximum Degree	Gross Standard Error			
		$\hat{V}(V)$	$\hat{A}(V)$	$\hat{A}(A)$	$\Delta\hat{V}(A)$
logarithmic	1	.097	.115	.101	.182
	2	.069	.083	.081	.166
	3	.062	.067	.081	.164
	4	.216	.292	.129	.173
	5	1.198	1.280	.534	.491
linear	1	.371	.615	.200	.281
	2	.249	.170	.134	.212
	3	.134	.088	.106	.196
	4	.150	.085	.111	.193
	5	.221	.136	.147	.265

characteristics of the best curve-fitting scheme (log/log cubic polynomials). Results suggest that either of these methods probably approaches the limits of data accuracy.

#### Conclusions

94. In one sense, numerical interpolation methods are preferable to fitted curves because the former are more flexible and do not rely strongly upon particular forms or curve shapes. Interpolation requires storage of and access to the entire table, however, as opposed to a few parameters in the case of a fitted function. Fitted curves also provide some smoothing of the entries in the table which may serve to filter errors.

95. Based upon relative errors, storage requirements, and computational considerations, log/log cubic polynomials seem to be the best alternative for summarizing hypsographic curves, given data of the type examined here. The approximate equivalence of the  $\hat{V}(V)$  and  $\hat{A}(V)$  error statistics indicates that storage of the parameters of the volume curve alone would be adequate as a basis for estimating both area and volume. Algebraic differentiation of the volume polynomial can be used to estimate area at any given depth. Thus, both the area and volume curves can be summarized by a total of four polynomial parameters according to the following scheme:

$$Z^* = \log_{10} (E - E_0) \quad (18)$$

$$V^* = \log_{10} (V) \quad (19)$$

$$A^* = \log_{10} (A) \quad (20)$$

$$V^* = c_0 + c_1 Z^* + c_2 Z^{*2} + c_3 Z^{*3} \quad (21)$$

$$A = (c_1 + 2c_2 Z^* + 3c_3 Z^{*2}) V / (E - E_0) \quad (22)$$

For cases in which data from only a few elevations are available and/or the quadratic or cubic terms do not add appreciably to accuracy (as assessed via stepwise polynomial regression), first- or second-order polynomials may be used.

96. Use of the method requires knowledge of the base elevation,  $E_0$ . If not available, it can be estimated approximately by extrapolating a plot of  $V^{1/3}$  vs.  $E$  to the horizontal axis. Any error in  $E_0$  estimated in this way would be offset in subsequent estimation of the polynomial coefficients.

97. The same functions can be used in very data-limited situations in which only estimates of mean depth, maximum depth, and surface area are available. Approximate parameter estimates in this case are given by:

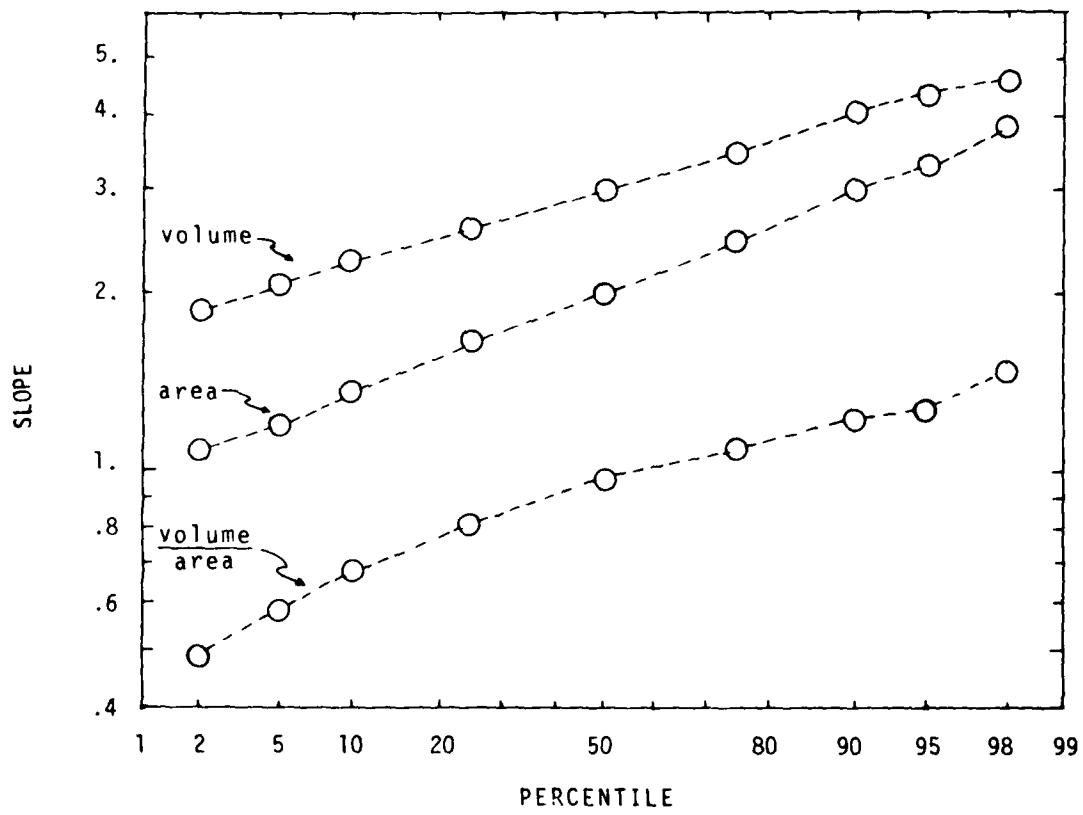

$$c_2 = c_3 = 0 \quad (23)$$

$$c_1 = z_{\text{max}} / z_{\text{mean}} \quad (24)$$

$$c_0 = \log_{10}(A z_{\text{mean}}) - c_1 \log_{10}(z_{\text{max}}) \quad (25)$$

98. To insure that the fitted polynomial is not used outside of the range of data availability, maximum and minimum elevations should also be stored with the fitted coefficients. It will be necessary to test the fitted coefficients to insure that the areas estimated through differentiation (equation (22)) are positive and increasing with elevation throughout the application range.

Distributions of Volume and Area Slope Parameters

PART XIII: VARIABILITY OF TROPHIC STATE INDICATORS IN RESERVOIRS

Introduction

99. The development and testing of empirical eutrophication models for reservoirs requires averaging of water quality measurements over spatial and temporal scales. If within-pool water quality variations are not random with respect to date, station, or depth, then summary statistics for a given reservoir will depend to some extent upon the particular data-reduction method employed. The choice of reduction method may, in turn, influence conclusions regarding the adequacy of existing models as well as the parameter estimates of any new models which may be developed.

100. There is no standard data reduction procedure which can be used prior to model development, testing, or application. Methods have included, for example: (1) taking the median or mean of all within-pool observations<sup>23</sup>; (2) sequential averaging over depths, stations, and dates<sup>29</sup>; (3) seasonal averaging within specific depth ranges<sup>30</sup>; and (4) various weighted-averaging schemes which reflect morphometric characteristics. As compared with natural lakes, many reservoirs pose special data reduction problems due to extreme spatial and/or temporal variations in conditions.

101. In this section, a subset of the current CE water quality data base is analyzed in order to describe spatial and temporal variations in trophic state indicators within a group of reservoirs. The analysis covers spatial relationships, seasonal relationships, variance components, and error estimation. Implications of the results are discussed with respect to the design of monitoring programs and use of the data in model development and evaluation. Details on many of the procedures used and results discussed below can be found elsewhere<sup>31,32</sup>

Data Base

102. EPA National Eutrophication Survey (NES)<sup>9</sup> data from 484 stations located within 108 CE projects have been used as a basis for this analysis. The relatively uniform sampling program designs used by the NES provide data which are suitable for statistical treatment. One drawback, however, is that under this program, reservoirs were typically sampled only three times during one growing season. In Phase II of this project, there are plans to examine data from other agencies, which, in many cases, are more intensive and/or cover longer periods.

103. Surface total phosphorus, Secchi depth, and chlorophyll-a values have been expressed in terms of Carlson's Trophic State Indices ( $I_p$ ,  $I_T$  and  $I_B$ , respectively)<sup>30</sup>:

$$I_p = 4.2 + 33.2 \log_{10} P \quad (26)$$

$$I_T = 60 - 33.2 \log_{10} Z_s \quad (27)$$

$$I_B = 30.6 + 22.6 \log_{10} B \quad (28)$$

where

P = total phosphorus concentration ( $\text{mg}/\text{m}^3$ )

$Z_s$  = Secchi depth (m)

B = chlorophyll-a concentration ( $\text{mg}/\text{m}^3$ )

The indices are calibrated such that the three versions are equivalent, on the average, when applied to midsummer, epilimnetic data from northern, natural lakes. Expression of measurements on the above scales tends to reduce the skewness in the distributions of the variables and provides benchmarks for assessing reservoir trophic state relationships in comparison to those typical of natural lakes. A statistical data summary is given in Table 41.

Table 41

Statistical Summary of EPA/NES Trophic Index  
Data from 108 CE Projects

Variable	n	mean	standard deviation	minimum	maximum
I <sub>P</sub>	1421	55.8	13.1	24.1	99.0
I <sub>T</sub>	1493	58.9	12.7	25.4	112.9
I <sub>B</sub>	1505	48.2	10.3	8.0	81.6

### Case Studies of Spatial Relationships

104. Spatial variations typical of a few reservoirs are depicted in Figures 7-10. Mainstem stations are displayed in downstream order within each reservoir (not to scale) and mean values are plotted for each version of the Trophic State Index. These plots provide initial perspectives on the types of spatial trends and relationships which can be found in reservoirs and are important supplements to the more formal statistical treatment of the data presented in subsequent sections. The plots seem to illustrate a number of important controlling processes, which are discussed below in relation to each reservoir.

105. Figure 7 contains data from the White River system on the Arkansas/Missouri border. Four reservoirs are connected in series: Beaver, Table Rock, Taneycomo, and Bull Shoals. With the exception of Taneycomo, they are all deep reservoirs with hydraulic residence times in excess of 250 days. Trophic State Index behavior in the first reservoir, Beaver, is considerably different from that typical of the downstream impoundments. Concurrent reductions in  $I_p$  and  $I_T$  most likely reflect sedimentation and the three index curves do not converge until the dam. Once most of the sediment load has been removed in Beaver, agreement among the index curves is good at most downstream stations. Increases in Table Rock probably reflect the influence of a major point source which accounts for more than 70% of the total phosphorus loading to that reservoir. The relatively low values of  $I_B$  in Taneycomo can be explained by the direct influence of subsurface discharge from upstream Table Rock Dam. Taneycomo has a short hydraulic residence time (7 days) and surface water temperatures at the times when summer chlorophyll-a samples were taken roughly matched temperatures at the 100-foot level just above Table Rock Dam ( $\sim 15^{\circ}\text{C}$ ). Taneycomo's short hydraulic residence time is apparently insufficient to permit recovery of temperatures and algal populations from those typical of the Table Rock hypolimnion. Decreases in all versions of the index are evident moving downstream in Bull Shoals, and relatively stable conditions are reached over the last four stations.

Figure 7 White River System

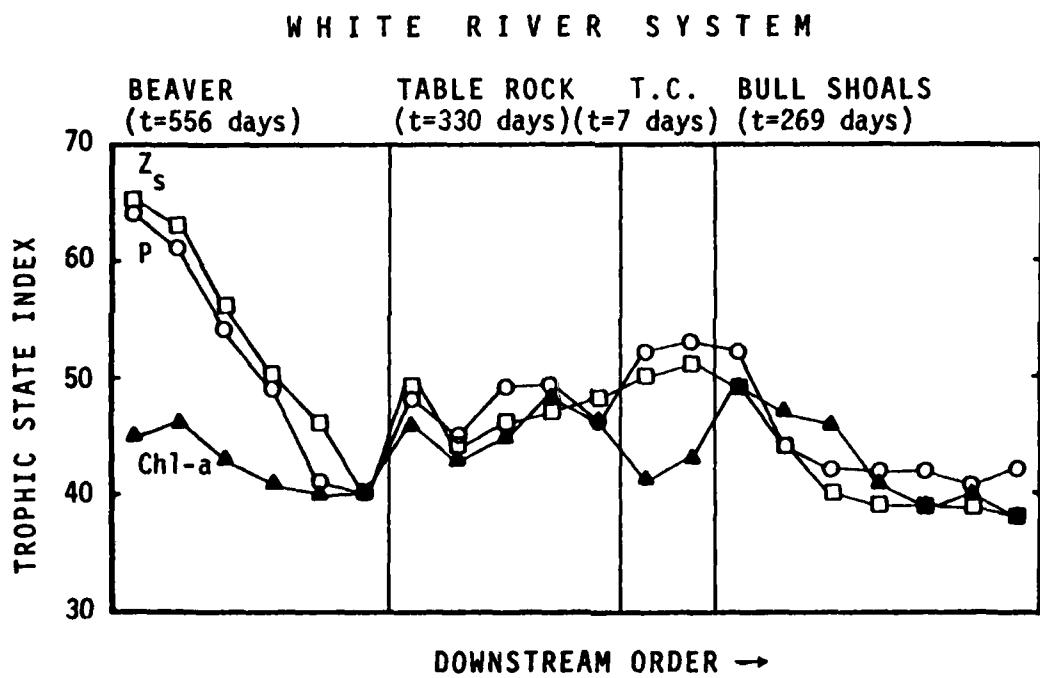

Figure 8 Sakakawea

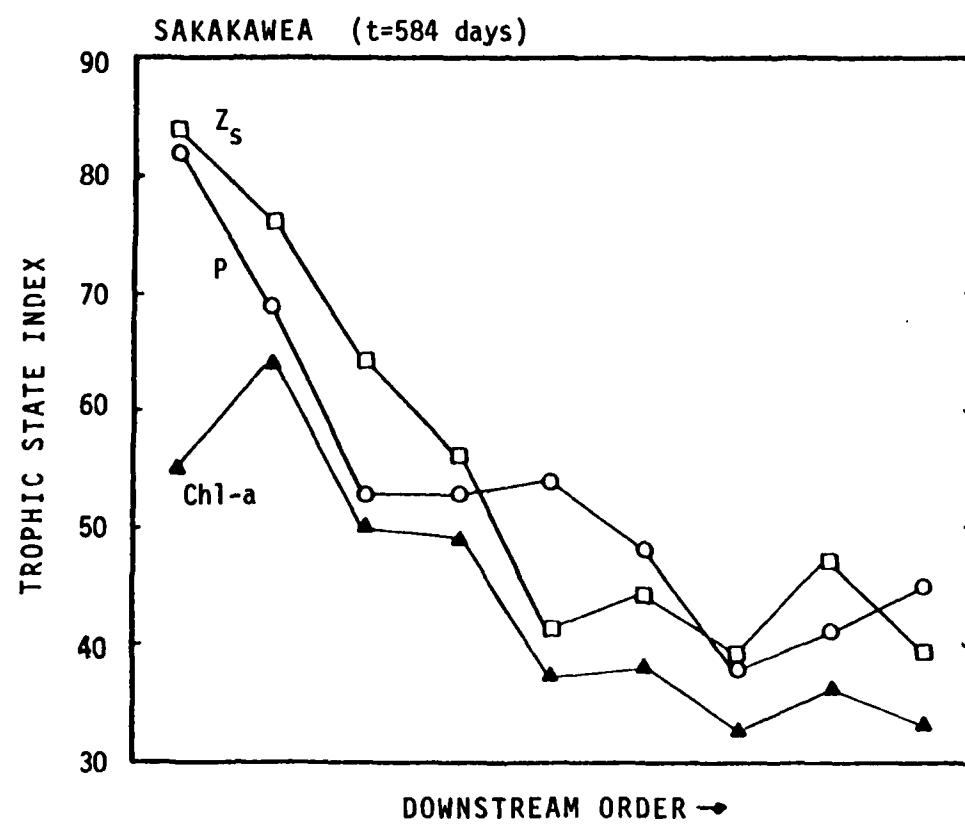

Figure 9 Old Hickory

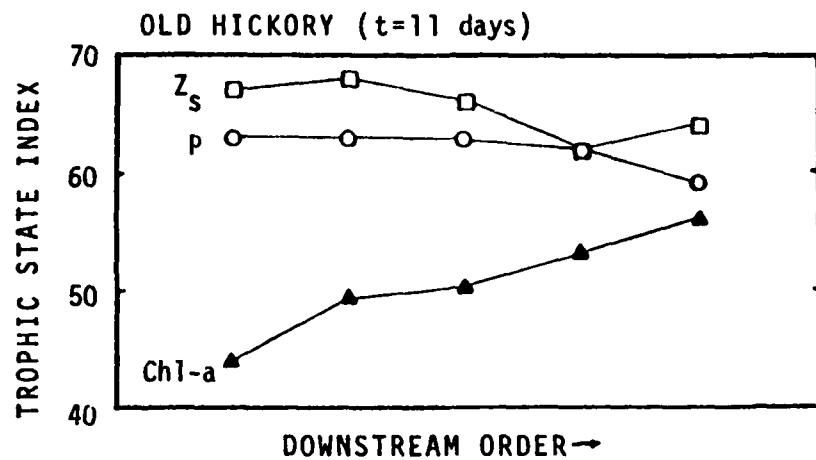

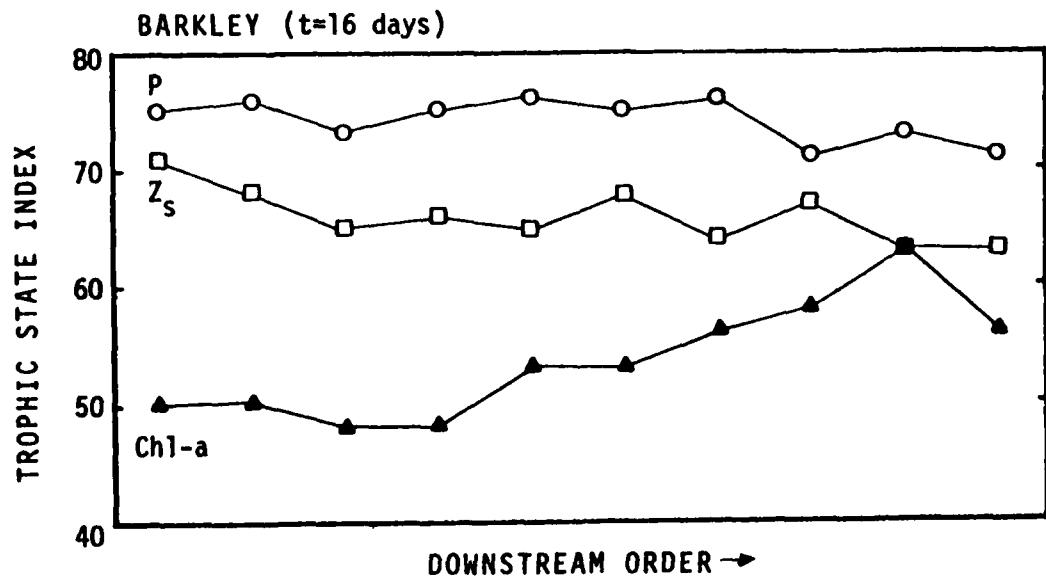

Figure 10 Barkley

106. Lake Sakakawea (Figure 8), on the Missouri River in Montana, shows TSI variations over 40 units, or sixteenfold differences in transparency and total phosphorus. Upstream portions were classified by the EPA/NES as "hyper-eutrophic" and stations near the dam as "oligotrophic". Below the second station, the chlorophyll-a index follows but remains roughly 5-10 index units below the phosphorus and transparency indices.

107. Old Hickory (Figure 9), on the Cumberland River in Tennessee, shows relatively small downstream reductions in phosphorus and transparency and a steady increase in chlorophyll-a. With a mean residence time of 11 days and sediment removal by upstream reservoirs on the Cumberland River, longitudinal variations in  $I_p$  and  $I_T$  are not as evident as in above panels. The gradual increase in  $I_B$  might be a hydraulic residence time effect, i.e., the time scale required for algal populations to "equilibrate" with available nutrient and light levels may be appreciable in relation to time-of-travel within the pool.

108. Similar behavior is evident in Lake Barkley (Figure 10), which is located further downstream on the Cumberland River and has a residence time of 16 days. One important difference is that the phosphorus index remains consistently higher than the other versions. Both ambient available nutrient concentrations and bioassays indicate, however, that algal populations in Lake Barkley were nitrogen-limited at the times of sampling. Use of  $I_p$  alone as a measure of nutrient availability may not be appropriate in this case.

109. The above case studies illustrate a number of factors which can be important in assessing reservoir trophic state relationships: sedimentation, upstream impoundment effects, hydraulic residence time effects, and nitrogen limitation. Reservoir hydrodynamics partially determine the transformations of these and other factors into spatial variations in the trophic state indicators. Upstream/downstream variations contain information on rates and directions of controlling processes. Graphing of spatial relationships and expression/analysis in terms of distance (river mile) and/or time (time-of-travel) will aid in quantitative data analysis and interpretation. Use of station means rather

than reservoir means seems to make more sense for model testing purposes.

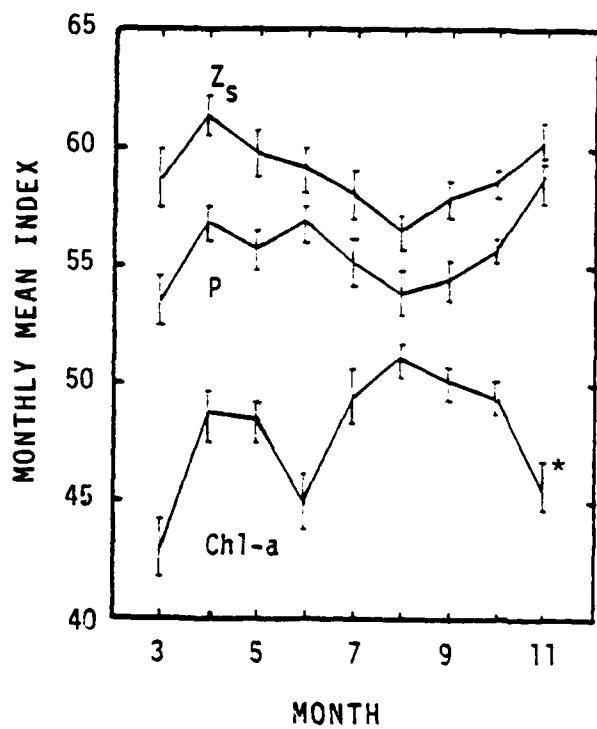

#### Seasonal Relationships

110. Average seasonal variations in the index components are depicted in Figure 11. Station means have been computed and their effects removed from the data prior to calculating the mean and standard error for each month (March-November) and index component. Analyses of variance indicate that monthly effects are significant ( $p < .0001$ ) for each component and strongest in the case of chlorophyll-a. The seasonal variations depicted in Figure 11 are characteristic of this collection of reservoirs but not necessarily of each reservoir individually.

111. Average seasonal effects on phosphorus and transparency are similar: both tend to be lowest during March and midsummer and highest during April and November, possibly reflecting seasonal flow and turbidity variations and influences of turnover periods. Monthly effects on chlorophyll-a suggest a spring maximum (April-May), followed by a June depression, a midsummer maximum, and lower values in November. Temperature and light effects may be responsible for the relatively low chlorophyll-a levels during March and November. The June depression may be due to seasonal succession of algal species. A more detailed examination of the data indicates that lower June chlorophyll-a levels are characteristic of about half of the stations sampled in June, while the rest have June levels more typical of May or July values. In testing seasonal aspects of TSI behavior, Carlson<sup>30</sup> also noted a June depression in chlorophyll-a index relative to the phosphorus index in three natural lakes.

112. Differences among various versions of the index provide a measure of "lake-like" behavior, since the index system is calibrated so that  $I_B$ ,  $I_T$ , and  $I_p$  values are equivalent, on the average, when applied to midsummer, epilimnetic data from northern, natural lakes. Figure 11 indicates that the range of index means is generally lowest during midsummer (approaching 5 during August) and highest during March, June, and November (approaching 15). Minor recalibration of the phosphorus and/or

Figure 11  
Monthly Variations in Trophic State Indices

\* mean  $\pm$  2 standard errors

transparency index would bring  $I_p$  and  $I_T$  into agreement for all seasons, since the monthly effect curves in Figure 12 are roughly parallel. Since seasonal chlorophyll-a behavior is fundamentally different, however, recalibration alone would not eliminate biases (i.e., significant differences between  $I_B$  and  $I_p$  or between  $I_B$  and  $I_T$ ) for all seasons.

113. Thus, seasonal factors must be considered in reducing the data and in recalibrating/redesigning the index system for use in reservoirs. One approach would be to restrict averaging period to midsummer. An alternative would be to include explicit seasonal effect terms in the model or index system. These approaches will be investigated in future model development work.

#### Variance Component Estimation

114. Two-way Analyses of Variance have been applied to each reservoir and index component to test for the significance of variations associated with station and sampling date. Results are summarized in Table 42. Significant ( $p < .1$ ) differences among station means in  $I_p$ ,  $I_B$ , and  $I_T$  were found in 46, 37, and 52 out of 105 projects, respectively. Significant differences among date means were found in 62, 67, and 64 projects, respectively.

115. The following ANOVA model has been employed to derive pooled estimates of the variance components of each version of the index:

$$y_{hij} = \mu + r_h + s_{hi} + t_{hj} + e_{hij} \quad (29)$$

where

$y_{hij}$  = index measurement in reservoir  $h$  at station  $i$  on date  $j$

$\mu$  = grand mean

$r_h$  = average effect of reservoir  $h$  on grand mean

$s_{hi}$  = effect of station  $i$  in reservoir  $h$

$t_{hj}$  = effect of date  $j$  in reservoir  $h$

$e_{hij}$  = random effect

Table 42  
Summary of ANOVA Results

Significant	35	32
<b>Transparency Index</b> -----		
Not Significant	27	14
Significant	26	38

\* number of projects in category (total = 105)

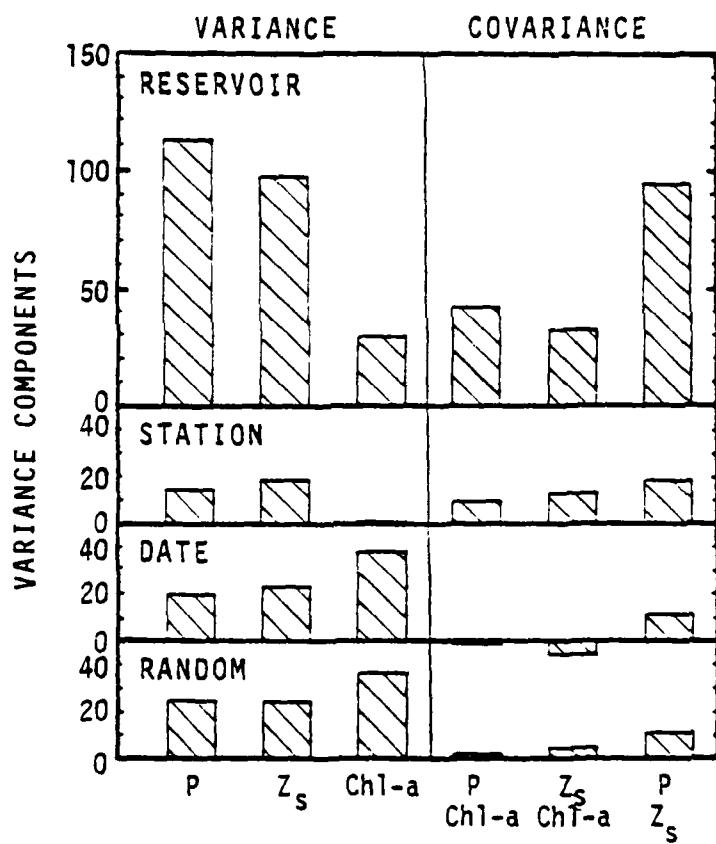

\*\* significance defined at  $p < .10$

The relative magnitudes of the within- and between-reservoir components are of special significance to monitoring and modelling efforts. With relatively large within-reservoir components, it would be difficult to obtain much accuracy in reservoir summary statistics (e.g., reservoir mean) with limited data. This would reduce the explainable variance ( $R^2$ ) of any model calibrated to the reduced data set, make it more difficult to distinguish among alternative model formulations, and increase the error associated with model parameter estimates.

116. SAS procedures<sup>2</sup> have been used to estimate the above variance components for each index separately and to estimate analogous covariance components for each pair of indices ( $I_B/I_T$ ,  $I_B/I_P$ ,  $I_T/I_P$ ). Results are shown in Figure 12. The phosphorus and transparency index components exhibit similar patterns: between-reservoir differences account for 60-66% of the total index variance, as compared with 29% in the case of chlorophyll-a index. Between-reservoir variances indicate that differences in chlorophyll-a are considerably less marked than would be predicted based upon differences in the phosphorus or transparency indices. Conversely, there is greater temporal and random variance in chlorophyll-a than in phosphorus or in transparency.

117. The covariance components on the right-hand side of Figure 12 provide some insights into relationships among the indices at different averaging levels. The between-reservoir and between-station covariance components are positive in all cases. Thus, the various versions of the index correlate positively both among reservoirs and among stations within reservoirs. Temporal components indicate a positive covariance for phosphorus/transparency but slightly negative covariances for the pairs involving chlorophyll-a. Thus, when temporal variations at a given station are analyzed, one would expect, on the average, to find a positive correlation only between the phosphorus and transparency indices. This correlation might be attributed, for example, to turbidity variations following seasonal or short-term (storm-event) flow variations. Despite its positive covariance between reservoirs and between stations, chlorophyll-a does not covary temporally with the other indices.

Figure 12  
Variance and Covariance Components of Trophic State Indices

118. The EPA/NES data base includes measurements from one growing season within any reservoir and does not permit testing for between-year variance or covariance components. Thus, it is not possible with this data set to test for year-to-year covariance between chlorophyll-a and phosphorus or transparency. Distinguishing between seasonal and year-to-year variance components will be possible with an expanded data base including data from other agencies and monitoring programs.

#### Error Analysis

119. The above analyses demonstrate that within-reservoir variations cannot be considered random with respect to dates or stations, the primary parameters used in monitoring program design. This has implications for estimating the accuracy of reservoir or station mean values calculated from the data set. If variations were random and serially independent with respect to station and date, the following statistic would be appropriate for estimating the variance of a reservoir mean:

$$\text{Var}(\bar{y}) = \frac{\text{Var}(y)}{N} \quad (30)$$

where

N = total number of observations within a reservoir for a given index

Using two-stage sampling theory<sup>33</sup>, the following formula is more appropriate:

$$\text{Var}(\bar{y}) = \frac{\sigma^2_s}{n_s} + \frac{\sigma^2_t}{n_t} + \frac{\sigma^2_e}{N} \quad (31)$$

where

$\sigma^2$  = mean squared deviation

$n_s$  = number of stations sampled

$n_t$  = number of dates sampled

The first term accounts for the influence of between-station variations, the second for between-date variations, and the third for random

variations. Note that equation (31) reduces to equation (30) when spatial and temporal variations are insignificant ( $\sigma_s^2 = \sigma_t^2 = 0$  and  $\text{Var}(y) = \sigma_e^2$ ). Because both spatial and temporal variations often exhibit patterns or trends (see Figures 7-11), they cannot be considered serially independent. Thus, equation (31) provides error variance estimates which are approximate but useful for assessing the relative contributions of spatial and temporal variance to the variance of reservoir means.

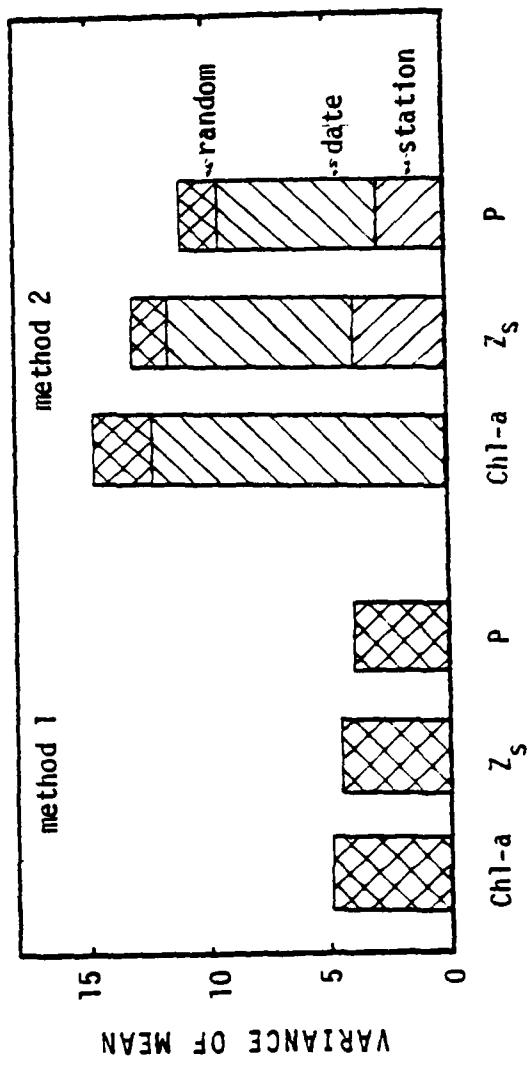

120. Based upon the total number of observations, stations, and reservoirs in the NES data set, the "typical" reservoir survey program covers 5 stations ( $n_s$ ) on 3 dates ( $n_t$ ), for a total of 15 observations (N). Using these values and the pooled variance components depicted in Figure 5, equations (30) and (31) have been applied to each version of the index and results are displayed in Figure 13.

121. Considering the effects of spatial and temporal variance components (equation (31)) increases mean error by about a factor of three over estimates derived from equation (30). Most of the error variance is due to the temporal component, especially in the case of the chlorophyll-a index. The error variances indicate that the EPA/NES sampling strategy has provided estimates of reservoir geometric means which are typically accurate ( $p < .05$ ) to within factors of 1.6, 2.2, and 1.7 for surface phosphorus concentration, chlorophyll-a concentration, and Secchi depth, respectively.

#### Monitoring Implications

122. Error analyses can be used to improve upon monitoring program designs. For example, given the objective of collecting data to be used in estimating a reservoir mean with minimum variance, the above results suggest that an increase in sampling dates would be more effective than an increase in sampling stations, because the date effect term dominates the error equation. Since the variance component estimates have been pooled, these results apply to this collection of reservoirs as a whole and not necessarily to each reservoir. The same approach could be

Figure 13  
Variance Components of Trophic Index Means within Reservoirs

applied using parameters estimated for each reservoir individually ( $n_s$ ,  $n_t$ ,  $N$ ,  $\sigma_s^2$ ,  $\sigma_t^2$ ,  $\sigma_e^2$ ). "Optimal" designs could be formulated based upon the error analysis framework and upon functions which relate  $n_s$ ,  $n_t$ , and  $N$  to monitoring cost. Given variance components estimated from prior monitoring data, improvements in program design (changes in  $n_s$ ,  $n_t$ , and  $N$ ) for a given reservoir could be formulated to yield minimum error for a fixed total cost or minimum cost for a fixed total error. The approach could be expanded to include depth as a third sampling dimension. This represents a logical application for the error analysis framework in a monitoring context.

#### Modelling Implications

123. In evaluating models, differences between observations and predictions can be attributed to three types of error: parameter error, data error, and model error. The first reflects uncertainty in the model coefficients, the second, errors in the predicted and/or predictor variables, and the third, influences of factors which are not considered in the model structure. Analyses of the type conducted above can be used to quantify potential data errors and separate them from the other components. This provides insights into the adequacy of a data base for use in model testing. If, for example, the data error component dominates, it would be difficult to distinguish among alternative models or to improve upon them without first improving the data base.

124. Table 43 summarizes results of regression analyses which have been done to summarize relationships among the three versions of the index using station mean and reservoir mean values. Results further demonstrate the need for recalibration of Carlson's index system in applications to reservoirs. The sensitivity of the chlorophyll-a component to phosphorus or transparency ranges from .30 to .37 and is in all cases significantly different from 1.0, the value obtained when the index system is calibrated to natural lakes. In contrast, the sensitivity of  $I_p$  to  $I_T$  is .88 for stations means and .91 for reservoir means.

Table 43  
Regression and Corresponding Error Analyses

Model	r	$s_b$	*** Total** Error	Sampling* Error	<u>Sampling Error</u> <u>Total Error</u>
<b>Station Means (n=484)-----</b>					
$I_B = 28.7 + .35 I_P$	.55	.024	42.3	23.1	.55
$I_B = 30.0 + .31 I_T$	.46	.027	47.6	22.7	.48
$I_P = 4.0 + .88 I_T$	.83	.027	47.6	25.9	.54
<b>Reservoir Means (n=108)-----</b>					
$I_B = 28.0 + .37 I_P$	.59	.048	32.5	16.3	.50
$I_B = 31.0 + .30 I_T$	.44	.059	41.0	16.0	.39
$I_P = 2.0 + .91 I_T$	.83	.059	41.0	22.1	.54

\* Sampling Error due to error in estimating mean index values within each station or reservoir; sampling errors for station mean phosphorus, chlorophyll-a , and transparency indices are estimated at 14.3, 21.3, and 15.0, respectively;corresponding sampling errors for reservoir-means are 11.2, 14.8, and 13.1.

\*\* Total Error = mean squared residual

\*\*\*  $s_b$  = standard error of regression slope

While the correlation coefficients (and explained variance) are considerably lower for predicting chlorophyll-a (.44-.59) than for predicting phosphorus from transparency (.83), the mean squared prediction errors are similar.

125. Part of the mean squared error for each regression model can be attributed to sampling error in estimating the reservoir and station mean values. The sampling error component of the mean squared error for each model is estimated from:

$$\text{Var}(\bar{y} - b\bar{x}) \approx \text{Var}(\bar{y}) + b^2 \text{Var}(\bar{x}) \quad (32)$$

where,

y = predicted index

x = predictor index

b = slope of regression model

Results of error analyses have been used to estimate sampling errors in station mean and reservoir mean values. Results indicate that roughly half (39-54%) of the residual standard error can be attributed to sampling error in the data values. The remaining variance presumably reflects model error, or the effects of factors (e.g., season, sediment) which are not accounted for in the model. The choice of averaging method (stations vs. reservoirs) does not influence the model coefficient values significantly. Mean squared errors are reduced when reservoir mean values are used, partially resulting from a reduction in the sampling error component. The standard errors of the regression slopes, however, increase roughly twofold when reservoir mean values are used in place of station means. Thus, using station means permits better definition of model coefficients.

126. The intent of the regression analyses presented in Table 43 is to demonstrate the error analysis approach and identify influences of data reduction method. The models suggest that chlorophyll/phosphorus and chlorophyll/transparency relationships in these reservoirs are significantly different from those which are typical of natural lakes.

The models are inadequate for predictive use, however, because a number of important factors have not been considered, including season, nitrogen limitation, hydraulic residence time, region, and external sediment loading. These and other factors will be considered in developing a Trophic State Index system applicable to reservoirs under Phase II of this project.

#### Conclusions

127. Statistical models of index (or water quality) variations within reservoirs have been shown to be complicated by the effects of spatial and temporal variations and by non-randomness or serial dependence in these variations. The above analyses have demonstrated how some of these influences can be approximately treated and applied to assess data adequacy for computing reservoir means and to improve upon monitoring program designs. A more thorough statistical treatment would require more intensive data sets and involve the construction of more complex statistical models applied separately to each reservoir using simulation techniques. This level of detail is not justified or feasible within the context of this study.

128. The following general conclusions can be drawn from the analyses of EPA/NES data in previous sections:

- a. Spatial relationships among trophic state indicators are important in some reservoirs, especially when stations are viewed in downstream order.
- b. Analyses of Variance indicate that within-reservoir variations are often non-random with respect to stations and/or sampling dates within a given year. Variations with respect to date are typically stronger than variations between stations, particularly in the case of chlorophyll-a.
- c. Some of the temporal variance within reservoirs and stations is fixed with respect to month or season. Seasonal effects on phosphorus are qualitatively similar to seasonal effects on transparency but differ from seasonal effects on chlorophyll-a.

- d. Between-reservoir variance in Carlson's chlorophyll-a index is roughly one third of the between-reservoir variances in the phosphorus and transparency indices.
- e. For this data set, chlorophyll-a variance between sampling dates within reservoirs is greater than its variance between reservoir means. The reverse is true for phosphorus and transparency.
- f. Covariance components indicate significant positive correlations among the three versions of the index system when variations between reservoirs and between stations within reservoirs are considered. The chlorophyll-a index does not correlate with either of the other indices, however, when temporal variations (at a given station or within a given reservoir) are considered.
- g. Because of non-randomness with respect to stations and dates, the error variance of reservoir mean values for each index are typically three times those estimated from the familiar formula for mean variance ( $\sigma^2/n$ ).
- h. Given the objective of estimating reservoir means with minimum variance, error analyses indicate that increases in the number of sampling dates would be generally more effective than increases in the number of stations per reservoir for improvement in the EPA/NES sampling design.
- i. Regression analyses indicate that chlorophyll-a levels are significantly less sensitive to phosphorus or transparency, as compared with the natural lakes used in developing Carlson's index system. Future development of an index system for reservoirs should consider the effects of season, region, nitrogen limitation, residence time, and sediment loading.
- j. Use of station means, as opposed to reservoir means, in recalibrating the index system causes small increases in standard error of estimate but substantially reduces the standard errors of model parameters.

#### Implications for Data Reduction Strategies

129. The conclusions in the previous section suggest that the following data-reduction/analytical strategies be used in testing and developing models under Phase II of this project:

- a. Since spatial variations and trends have been shown to be often statistically identifiable and useful for interpretation purposes, use of station means would seem to be more

desirable than use of reservoir means for model testing. Use of station means would also permit better definition of model parameters.

- b. It would be useful to develop a scheme for spatial orientation of stations within each reservoir with respect to major tributary (arm) and distance (river mile). Some aggregation of stations based upon proximity may be feasible within this framework.
- c. Seasonal factors should be considered in averaging data within each station or station group. This would involve, for example, estimation of "spring", "summer", "fall", as well as "growing season" and "annual" averages.
- d. For non-NES stations which are sampled during more than one year, tests for significant year-to-year differences should be made and used to decide whether aggregation of data from different years is justifiable.
- e. While the above analyses have been based exclusively upon surface sampled for phosphorus, averaging with depth should be considered, at least within the photic zone, for testing of relationships among phosphorus, chlorophyll-a, and transparency.
- f. To permit testing of loading response models, seasonal estimates of reservoir means could be derived by averaging across stations. Due to longitudinal variations in many reservoirs, however, near-dam or discharge conditions should also be used as bases for loading model evaluations.

PART XIV: EVALUATION OF METHODS FOR ESTIMATING PHOSPHORUS LOADINGS

Introduction

130. The estimation of reservoir nutrient budgets entails estimation of the total mass of nutrients passing given sampling points over a given period of time, typically at least one year. While continuous, flow-weighted composite sampling for concentrations would provide the best basis for deriving such estimates, usually only periodic grab-samples are available for stream concentrations. These concentrations must be integrated with flow records (typically continuous) in order to estimate the desired loadings. The purpose of this section is to test and compare alternative methods in order to provide some guidance for future nutrient budget calculations on CE reservoirs.

Preliminary Analysis

131. The relationship between concentration and flow influences the appropriateness of a given loading calculation method at a given station. A subset of flow and phosphorus concentration data from the current CE data base has been analyzed in order to provide some perspective on this relationship<sup>34</sup>. The subset includes 86 tributary and 33 discharge stations, each with at least 25 total phosphorus/streamflow pairs obtained from STORET. Table 44 describes the symbols and fundamental equations used to characterize flow and concentration variations.

132. Results of the preliminary analysis are given in Table 45, with data grouped by station type. The regression model relating the logarithm of concentration to the logarithm of flow explains, on the average, 12.3% of the variance in concentration at tributary stations and 6.6% of the variance in concentration at discharge stations. Figure 14 shows that the upper percentiles of the  $R^2$  distribution at tributary sites are roughly twice those found at discharge sites.

Table 44  
Fundamental Equations and Symbols

Loading Definition:       $L = Q C$   
 $W = X + Y$

Flow/Concentration Model:  $C = a Q^b$   
 $Y = \log_{10} a + b X$

Distributions:       $Y: (\text{mean} = \mu_y, \text{std.dev.} = \sigma_y)$   
 $X: (\text{mean} = \mu_x, \text{std.dev.} = \sigma_x)$

Symbols:       $L = \text{Loading (mass/time)}$   
 $Q = \text{Flow (volume/time)}$   
 $C = \text{Concentration (mass/volume)}$   
 $W = \log_{10}(L)$   
 $X = \log_{10}(Q)$   
 $Y = \log_{10}(C)$   
 $a, b = \text{Regression model parameters}$

Table 45

## Preliminary Analysis of Flow/Total P Concentration Relationships

Statistic	Station Type	
	Tributary	Discharge
number of stations	86	33
fraction of variance explained by regression model	.123 ± .151*	.066 ± .078
residual variance	.101 ± .075	.090 ± .050
serial correlation of residuals	.228 ± .205	.300 ± .276
conc/flow sensitivity (b)	.124 ± .250	.097 ± .138
standard dev. of $\log_{10}$ (flow)	.573 ± .246	.600 ± .303
standard dev. of $\log_{10}$ (conc)	.323 ± .133	.297 ± .088

\* mean ± one standard deviation

Figure 14  
Distributions of  $R^2$  Values at Tributary and Discharge Stations

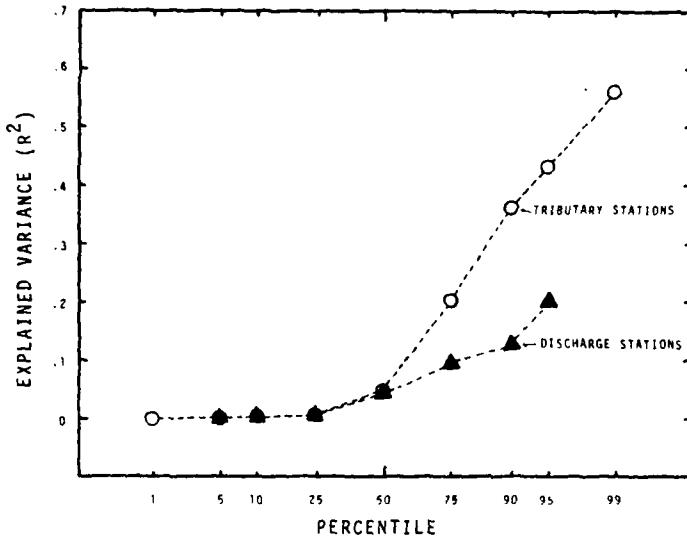

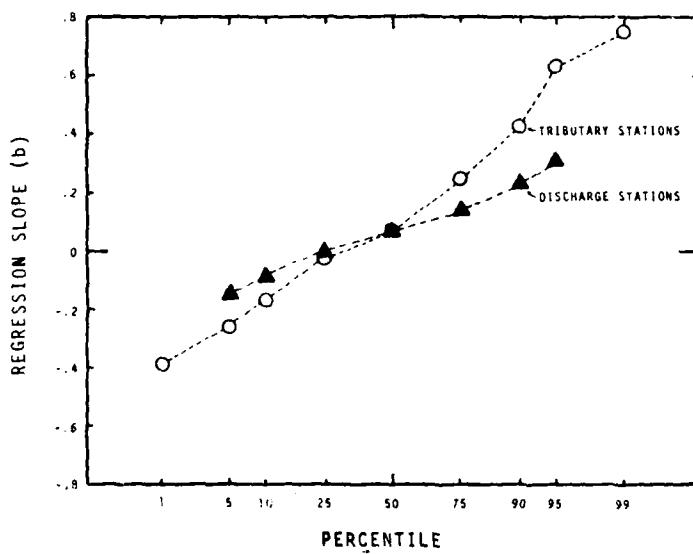

Figure 15  
Distributions of Regression Slopes at Tributary and Discharge Stations

133. Both the mean and the standard deviation of the regression slope ( $b$ ) are larger in the case of tributary stations. The distributions of  $b$  are compared on a normal probability scale in Figure 15. While the medians are nearly equal, the upper percentiles are higher and the lower percentiles are lower in the case of tributary stations. The wide distribution of  $b$  values across stations suggests that loading calculation methods must be capable of accounting for alternative flow/concentration relationships.

134. These results indicate that concentration tends to be more flow-dependent at upstream tributary stations than at discharge stations. Reservoir pools may buffer variations associated with runoff events (which would tend to produce high  $b$  values) or point source discharges (which would tend to produce low  $b$  values). The fact that streamflow is highly regulated at reservoir discharge points may also contribute to weaker flow/concentration relationships. The serial correlation of residuals (i.e., concentration, after the effect of flow is removed) tends to be higher in the case of discharge stations (.30 vs. .23 on the average). This suggests that seasonal factors or long-term trends may have greater influences at discharge points.

135. Table 46 lists means regression slopes by station type and component (dissolved P, total P-dissolved P, and total P, respectively). This breakdown is based upon measurements of total P and dissolved P at 52 tributary and 17 discharge stations. For both station types, the mean slopes of dissolved phosphorus with respect to flow are not significantly different from zero. In the case of total P-dissolved P, however, the mean slope is  $.34 \pm .05$  at tributary stations and  $.11 \pm .09$  at discharge stations, although the latter is not significantly different from zero. The influence of streamflow on the transport of particulate phosphorus probably accounts for these results. The dissolved component tends to be more independent of flow than the particulate component. The relative weakness of the dissolved phosphorus/flow relationship may reflect a buffering effect of adsorption chemistry on stream phosphorus levels and/or the fact that transport efficiency for dissolved phosphorus

Table 46

## Concentration/Flow Sensitivities by Component and Station Type

<u>Component</u>				
Station Type	Number of Stations	Total P - Dissolved P	Dissolved P	Total P
Tributary	52	.341 ± .050*	.019 ± .034	.239 ± .044
Discharge	17	.109 ± .087	.036 ± .101	.082 ± .038

\* mean ± one standard error of mean

is not velocity-dependent, as in the case of the particulate fraction.

#### Estimation Methods

136. Four algorithms for estimating loadings have been tested:

- a. average loading.
- b. average concentration x average flow.
- c. flow-weighted average concentration x average flow.
- d. regression estimate based upon log (concentration) vs. log(flow) relationship.

These schemes are described in Table 47. A few other types of regression models have also been evaluated, but none proved better than the model used in Method 4 (see Table 47). Two approaches to evaluating these methods have been taken: one involves subsampling from simulated flow and concentration data and the other, subsampling from real flow and concentration data. These methods and results are described below.

#### Tests Based Upon Simulated Data

137. Table 48 describes an algorithm used to generate flow and concentration time series using Monte-Carlo techniques. This method has been used to produce five years of simulated daily-average flow and concentration data. Mean loadings have been calculated directly for each year and compared with estimates based upon subsampled taken at monthly intervals and employing the calculation methods listed in Table 47. For each year, a total of thirty trials (sets of subsamples) have been made, representing regular sampling on day 1 to day 30 of each month, respectively. Thus, error statistics are based upon a total of 150 trials for each method. Results have been found to be insensitive to the number of trials. The simulation algorithm is not adequate for evaluation of interpolation methods (in which the sequence of samples is considered), since no serial correlation or seasonal factors are included. The parameters of the simulation model are typical of the

Table 47

## Estimation Methods

Method 1 : Average Loading

$$\hat{L}_1 = \frac{\sum q_i c_i}{n}$$

Method 2 : Average Concentration x Average Flow

$$\hat{L}_2 = \bar{Q} \frac{\sum c_i}{n}$$

Method 3 : Flow-weighted Average Concentration x Average Flow

$$\hat{L}_3 = \bar{Q} \frac{\sum q_i c_i}{\sum q_i}$$

Method 4 : Regression Estimate

$$\hat{L}_4 = \frac{\sum q_i c_i}{n} \left[ \frac{n \bar{Q}}{\sum q_i} \right]^{b+1}$$

where,

$q_i$  = flow on sample date i

$c_i$  = concentration on sample date i

n = number of sample dates

b = slope of  $\log(c)$  vs.  $\log(q)$  regression

$\bar{Q}$  = average flow over entire period, based upon continuous flow record

$\Sigma$  = sum over all sample dates (i=1 to n)

Table 48

Algorithm for Generation of Flow/Concentration Time Series

Input Values:

$\mu_x$  = mean of logarithm of flow = 0.  
 $\mu_y$  = mean of logarithm of concentration = 0.  
 $d_x$  = standard deviation of logarithm of flow = .52  
 $d_y$  = standard deviation of logarithm of conc = .26  
(random component)  
 $b$  = slope of flow/concentration model = (-.8 + .8)

Algorithm:

$$x_i = \mu_x + N(0,1)d_x$$
$$y_i = \mu_y + N(0,1)d_y + (x_i - \mu_x)b$$

Symbol:

$N(0,1)$  = normal random deviate with mean zero and standard deviation one

data distributions depicted in Figure 15 and Table 45. A range of flow/concentration sensitivities ( $b$  in Table 47) have been used (-.8 to +.8).

138. The following error statistics have been used to compare "observed" and estimated loadings for method and trial:

$$\text{Bias}_j = \frac{1}{M} \sum_{k=1}^M \left( L_k - \hat{L}_{jk} \right) / L_k \quad (33)$$

$$\text{MSE}_j = \frac{1}{M} \sum_{k=1}^M \left( L_k - \hat{L}_{jk} \right)^2 / L_k^2 \quad (34)$$

where,

$\text{Bias}_j$  = bias associated with method  $j$

$\text{MSE}_j$  = mean squared error associated with method  $j$

$M$  = total number of trials = 150

$L_k$  = actual loading for trial  $k$  (mass/time)

$\hat{L}_{jk}$  = estimated loading for method  $j$  and trial  $k$  (mass/time)

For each method, these error statistics are plotted vs. the flow/concentration sensitivity statistic in Figures 16 and 17, respectively.

139. Only Method 1 is unbiased for all values of  $b$ . The MSE of this method, however, is significantly higher than that of the other methods at values of  $b$  greater than -.2. This method is best under conditions where loading is relatively independent of flow ( $b > -1$ ). This might be the case, for instance, at a station which is located below a major point source of nutrients, but not where storm-event or non-point loads are significant.

140. The performance of Method 2, in which concentration and flow are averaged independently, is a strong function of  $b$ , both with respect to bias and variance. This method is unbiased only at  $b=0$ , but has biases of +35% and -23% at  $b$  values of -.2 and +.2, respectively. Trends in bias continue moving toward more negative or more positive  $b$  values. The method has a sharp minimum in MSE at  $b=0$ . This scheme is apparently best only when concentration and flow are truly independent, but gives

Figure 16  
Bias in Loading Estimates as a Function  
of Regression Slope and Estimation Method

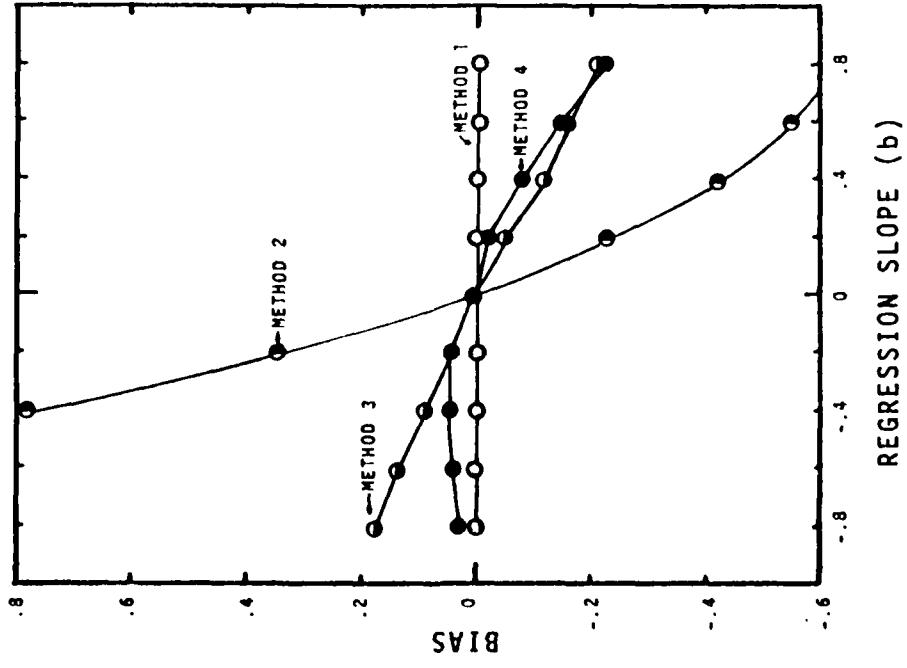

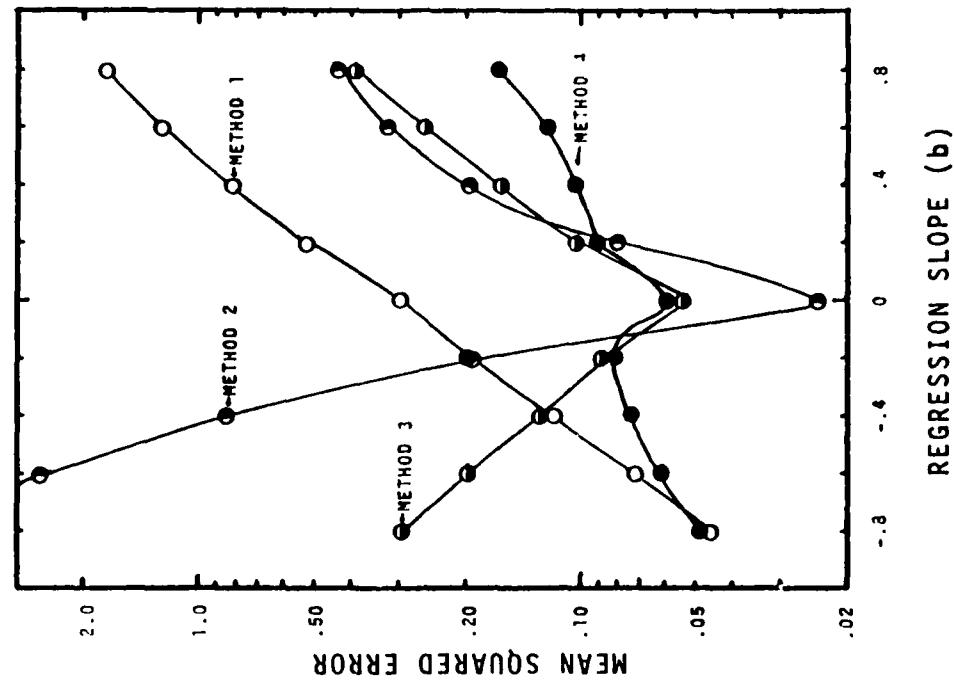

Figure 17  
Mean Squared Error in Loading Estimates as a  
Function of Regression Slope and Estimation Method

substantial biases and MSE's for even weak flow/concentration relationships.

141. Method 3, which employs the flow-weighted average concentration, behaves qualitatively similar to Method 2, but is not as sensitive to b values. Zero bias and minimum variance are evident at b=0. This method is analogous to a "ratio estimate" used in classical sampling theory.<sup>35</sup>.

142. Method 4 has less bias and variance than Method 3 for most b values. Unlike the other methods, the regression model can adjust to different types of flow/concentration relationships and estimation errors are less sensitive to b values. Bias becomes more significant at high values of b. At b=.6, for example, Method 4 underpredicts loading by an average of 15%. The MSE at this b value is .13, which corresponds to a standard error of  $\pm 36\%$ . Thus, bias is less than one half of one standard error and accounts for 17% of the MSE ( $.15^2/.13$ ) at b=.6. Additional tests indicate that applying the regression model separately to each daily flow in the year, a more tedious calculation, does not reduce the bias or variance of Method 4 at any b value.

#### Tests Based Upon Real Data

143. Calculation methods have also been tested using the flow and concentration data from the 119 stations analyzed above. Subsamples of 12 flow/concentration pairs have been taken at regular intervals from each station. Loadings estimated for each subsample and method have been compared with loadings estimated by applying Method 1 to all flow/concentration pairs available for each station. A total of 508 subsamples have been taken from 86 tributary stations and 190 subsamples from 33 discharge stations. Bias and MSE estimates are given in Table 49 for each method and station type. These results are approximate because of errors involved in estimating actual loading.

144. Generally, Methods 3 and 4 appear to perform better than Methods 1 or 2 for both station types. The MSE of Method 3 equals that

Table 49

## Results of Method Testing Using Real Flow and Concentration Data

<b>Statistic</b>	<b>Estimation Method**</b>			
	<b>Method 1</b>	<b>Method 2</b>	<b>Method 3</b>	<b>Method 4</b>
<b>Tributary Stations (N=86,M=508)</b>				
<b>Bias</b>	<b>-.002</b>	<b>-.027</b>	<b>-.029</b>	<b>-.023</b>
<b>MSE</b>	<b>.530</b>	<b>.297</b>	<b>.176</b>	<b>.176</b>
<b>Discharge Stations (N=33,M=190)</b>				
<b>Bias</b>	<b>.001</b>	<b>.068</b>	<b>-.017</b>	<b>-.000</b>
<b>MSE</b>	<b>.272</b>	<b>.585</b>	<b>.108</b>	<b>.156</b>

\* N = number of stations, M = number of trials

\*\* see Table 47

of Method 4 in tributary stations (.176), but is lower in discharge stations (.108 vs. .156). When averaged over the range of b values in the data set, none of the methods is appreciably biased.

#### Prior Error Estimation

145. To provide bases error analysis and assessment of data adequacy, a means for estimating the variance of loading estimates derived from a given set of flow/concentration data is needed. Table 50 presents a formula appropriate for use with Method 4 (or with Method 3 when  $b=0$ ). This approximate formula, derived from expected value theory, has two terms: one reflecting variance around the flow/concentration regression model, and one reflecting variance in the estimate of the slope parameter b.

146. Figure 18 compares the observed mean squared estimation errors for Method 4 with error variances estimated from the formula in Table 50 using simulated data. Reasonable agreement between observed and estimated variances is apparent over the range of b values typically encountered. Similar tests have been done using real flow and concentration data. The formula in Table 50 overestimates the error mean square by an average of 18% for tributary stations and underestimates the error mean square by an average of less than 1% at discharge stations.

#### Conclusions

147. Preliminary data analysis has characterized the distributions of flow/concentration relationships in tributary and discharge streams. Methods 3 and 4 are generally better than Methods 1 or 2 for estimating loadings, given the distribution of concentration/flow sensitivities encountered at various stations (see Figure 15). Method 3, which employs the flow-weighted average concentration, is actually a special case of Method 4, with  $b=0$ . In calculating loadings, it seems reasonable to use a regression analysis to estimate the slope parameter b and to use

Table 50

**Formula for Estimating the Variance of Loadings Calculated  
Using Method 4**

Loading Estimate:

$$\hat{L}_4 = \frac{\sum q_i c_i}{n} - \left( \frac{n \bar{Q}}{\sum q_i} \right)^{b+1}$$

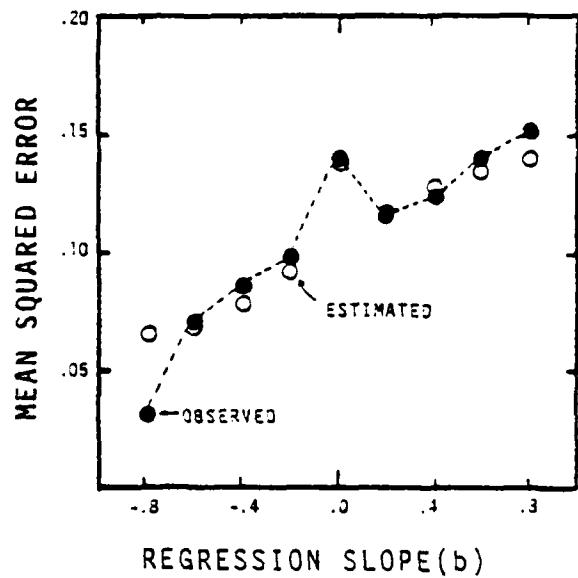

Variance:

$$V(\hat{L}_4) = \frac{\left[ \sum (q_i c_i - a q_i)^{b+1} \right]^2}{n(n-2)} + \left[ \frac{\sum q_i c_i}{n} \ln \left( \frac{\bar{Q} n}{\sum q_i} \right) \right]^2 \sigma_b^2 \cdot \left( \frac{\bar{Q} n}{\sum q_i} \right)^{2b}$$

\* where  $\sigma_b^2$  = variance of b estimate

\* other symbols defined in Tables 46 and 47

Figure 18  
Observed and Estimated Mean Squared Error in Loading Estimates

Method 4 unless the slope estimate is not significantly different from zero, in which case Method 3 would be used. The formula in Table 50 can be used to derive approximate estimates of error associated with a given mean loading calculated using Methods 3 or 4. Error variances can be used, in turn, to characterize the accuracies of reservoir nutrient loading and discharge estimates.

#### PART XV: CONCLUSIONS

148. The compilation, description, and preliminary analyses of the data base described in previous sections lead to the following conclusions:

- a. Using primarily centralized sources of information, it has been possible to compile sufficient data on water quality, hydrology, sedimentation, and other project characteristics to permit testing of empirical eutrophication models under Phase II of this study.
- b. The hydrology files need to be augmented with monthly elevation/contents data from several districts and projects.
- c. Information in the water quality files will not be adequate for assessing the trophic states of all 299 reservoirs in the central project list. It should be adequate, however, for characterizing about 130 reservoirs and for testing empirical models relating within-pool measures of trophic state.
- d. Use of data sources outside of the EPA/National Eutrophication Survey has generally more than doubled the total numbers of observations of various within-pool trophic state indicators. Non-NES data are generally more extensive temporally.
- e. Comparisons derived from the EPA National Eutrophication Survey compendium reveal significant differences between lakes and reservoirs in the means of most morphometric, hydrologic, and trophic state indicator variables. Compared with natural lakes, reservoirs have greater potential nutrient enrichment problems, as gauged by Vollenweider phosphorus loading models, but lower observed levels of chlorophyll-a, on the average. The validity of existing loading models in reservoirs is in question due to lake/reservoir differences in morphology, hydrodynamics, sedimentation, and region. Because of the relative geographical distributions of lakes and reservoirs in the U. S., it is difficult to distinguish the effects of region from those of impoundment type.
- f. For the purposes of this project reservoir hypsographic curves can be conveniently summarized using low-order polynomial equations relating the logarithm of total volume to the logarithm of total depth. Errors characteristic of this curve-fitting scheme are similar to those characteristic of direct interpolation methods.

- g. Within-reservoir variations of trophic state indicators generally cannot be considered random with respect to station and date, the primary parameters used in monitoring program design. Spatial variations contain information on rates and directions of processes controlling eutrophication within reservoirs. Variance component analyses indicate that phosphorus and transparency have variance structures which are similar to each other, but fundamentally different from the variance structure of chlorophyll-a. Implications of these variance structures for monitoring and modelling efforts have been discussed.
- h. A method for estimating the mean and error variance of nutrient loadings derived from continuous-flow and grab-sample-concentration measurements has been developed and tested using real and simulated flow/concentration time series. The method employs a regression model relating concentration to flow and has been shown to compare favorably with alternative calculation methods with respect to bias and variance of loading estimates under a range of conditions.

## PART XVI: RECOMMENDATIONS

149. The following additional data base development work is required in order to permit testing of empirical eutrophication models and should therefore be included in the scope of Phase II of this study:

- a. compilation of monthly elevation/contents data from many districts and projects, as indicated by the inventories in Appendix A.
- b. development of a scheme for sorting of water quality stations in downstream order within reservoirs.

150. While compiled for the specific purposes of this project, the data base described in this report could be adapted for other, more generalized uses. As discussed in the introduction to this report, the current data base consists of a number of computer files, reports, maps, and data forms organized in a consistent framework. It is not a system designed for frequent interactive use. Given the current data base, the development of such a system would involve the following:

- a. definition of objectives (desired scope of data base uses).
- b. definition of operating environment (direct users, maintenance personnel, and computer system).
- c. development of appropriate software for various purposes (e.g., accessing, updating, editing, summarizing, displaying, analyzing).
- d. compilation of any additional data required for intended uses of the data base (e.g., inclusion of priority pollutants, development of a digital reservoir mapping capability).
- e. appropriate modifications in file designs.
- f. establishment of channels and procedures for updating and verification of information.
- g. testing of the system in an operational environment.
- h. documentation of the system.
- i. orientation of potential users.

It is recommended that the Corps of Engineers consider expanding upon the existing data base, as outlined above, in order to permit more generalized use of the information which has been compiled under this project. The

final product would represent a valuable resource for reservoir design, operation, and research at various organizational levels within the Corps of Engineers.

In accordance with letter from DAEN-RDC, DAEN-ASI dated 22 July 1977, Subject: Facsimile Catalog Cards for Laboratory Technical Publications, a facsimile catalog card in Library of Congress MARC format is reproduced below.

Walker, William W.

Empirical methods for predicting eutrophication in impoundments : Report 1 : Phase I, data base development / by William W. Walker, Jr. (Environmental Laboratory, U.S. Army Engineer Waterways Experiment Station). -- Vicksburg, Miss. : The Station ; Springfield, Va. : available from NTIS, [1981].

153, 55 p. : ill. ; 27 cm. -- (Technical report / U.S. Army Engineer Waterways Experiment Station ; E-81-9).

Cover title.

"May 1981."

"Prepared for Office, Chief of Engineers, U.S. Army, under Contract DACW 39-78-0053, EQWOS Work Unit IE."

"Monitored by Environmental Laboratory, U.S. Army Engineer Waterways Experiment Station."

Bibliography: p. 151-153.

1. Computer programs. 2. Eutrophication. 3. Mathematical models. 4. Prediction theory. 5. Reservoirs.
